----------Folks, This is my first post to the group as a new TS-820Sowner. Purchased a (sorta) workingebay “project” TS-820S in August and did a good bit of troubleshooting and workto get it fully functional again. I wanted to share a couple of restoration experiences I had with the rigin case they might be useful for others in the group. The rig was in fair shape for it’s age and the main problemswere 1) low output—70-80 watts—on all bands and 2) digital display fixed offseterrors on all bands. TRANSMITTER HACK—SUBSTITUTE BIAS CIRCUIT RESISTOR; CHINESEFINALS I had low output from the JAN 6146W’s and a maximum of 50 maidle plate current despite the bias pot being turned fully up. The -C voltage was well out of spec(high negative). After some head scratching, I found that a previous owner hadsubstituted a 3.3k resistor the 12k R25 resistor in the bias circuit on the RFboard. After I put in a new 12Kresistor, I got nothing from the finals so I replaced them with new (Chinese!)6146B’s and the transmitter has tuned and operated perfectly since and the biasadjustment is now mid-range again. Anyone else seen this hack? Whether this was a QRO hack or whether the owner was justtrying to get the last life out of old finals I can’t tell, but it’s workingvery well now. I know the China tubes don’t enjoy the best reputation on-line,but I cooked them for 3 hours or so before use, neutralized them per Ken’s (K4EAA) procedure and they have behavedperfectly since with full 100W on all bands, including 10M. DIGITAL DISPLAY OFFSET ERROR FIX—NOT A SOLDER PROBLEM! WRONG CIRCUIT DIAGRAM IN SERVICE MANUAL This digital readout problem was unlike any I’d seen online. The readout was stable andtracked the VFO on all bands, but had a different fixed offset error on everyband. Troubleshooting revealedthat the 1K oscillator frequency was 1667 Hz instead of 1000 Hz due to a baddivider chip (IC3, Toshiba TD3490BP) in the Counter Mix board oscillator. I replaced it with a TI SN74LS90N perTerry (K9TW) (Mouser PN 595-SN74LS90N) and this solved the problem. Troubleshooting the DG-1 was complicated by the fact thatthe Counter Mix board circuit diagram in my Service Manual (and every other oneI could find on line) didn’t match my unit. It turns out that the on-line TS-820S manuals I’ve seen arefor older units that have the original digital display tube (LD-8109 tube withconnector on one end of the tube with display assembly number

X54-1170-00). Mine had the later display tube (LD-8135 tube with connectorson both ends of the tube, display assembly number X54-1310) that apparentlyalso uses a different Counter Mix board, even though the board part numbers arethe same. The CM boards areidentical except for the calibration oscillator circuit. I was finally able to find the correct Counter Mix board circuitdiagram in the TS-820S Operating Manual on page 29 at this link:
http://www.wb4hfn.com/KENWOOD/Manuals/TS820S%20Operating%20Manual_02_W0NTO.pdf
INVALUABLE RESOURCES Terry (K9TW) has my everlasting gratitude for guiding methrough the troubleshooting of these two problems. He was very patient through a lot of email threads to helpget my 820S back on its feet despite being very busy—the man knows his stuff! I also took advantage of a number of excellent on-linechecklists, tutorials, how-to's, component sources, manuals and referencesavailable from Ken (K4EAA), Ron (WB4HFN), Mike (W5RKL), Ward (KG6HAF), Gordon (N6WK),and Jim (KE7OAY). These guided methrough a lot of other work on this unit (in addition to the above!). I am amazed by all the outstandingresources available on-line and grateful for their dedication to these classicrigs! DaveKC3CIPBoothedw@...

Thanks Joe and Dave for this post on the TS-820S. Earlier this summer, my friend gave me his TS-820 and MC-50 that he had purchased new. When he made this purchase, he installed the optional CW filter and digital display unit. There were never any mods, tubes or anything replaced in the rig, and he never used it on CW. Many of these radios were converted for CB use. Plus, very few hours of use on it and not a scratch on it either! Later, I bought on auction, a SP-820 and remote VFO-820 making for a nice operating vintage station. It was nice to have a old rig that I got in perfect condition and I didn't have to do a thing with it! 73, de Karl, KO8S

From: Donald Allen
Topic: 49870 Message: 49871

The Shure 444 is an excellent mic to use with the TS-520. The MC-50 is OK, especially if you cover the outer circumference rib openings, but even with that mod from the '70s and early '80s, the 444 is my 1st choice. And, I have both...

I agree but you must pay attention how close you are to the microphone and how loud you talk. It's easy to over drive the speech amplifier with the 444 so keep about an inch or so away from the microphone and talk in a "normal" tone of voice. Set the meter switch to ALC and the MIC gain fully CCW. While talking in a normal tone of voice adjust the MIC gain until the ALC meter peaks in the middle of the ALC scale then stop adjusting the MIC gain. A lot of people tend to talk too close to the microphone, you can hear this on the air by the "breath" noise heard when the operator is talking. I have a 444 and used it with an TS-820S I had a few years ago, worked very well, didn't need the processor turned ON.

I see RF Parts sells not only the 6146B tube but also the 6146BMP. I ask what is the difference. Cid, K2CID

49877. Re: [TS-520_820_530_830] 6146B tubes

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-19 02:42:16 UTC
From: Craig Roberts
Topic: 49876 Message: 49877

The "MP" designates a "matched pair". Matched pairs of finals are unnecessary in our hybrid use.

A caveat: the 6146B tubes offered by RF Parts may be the Taylor brand now made in China. They have demonstrated some quality control problems in the past. The older U.S. made GE, RCA and Sylvania tubes are more consistently good, though I did experience the instant-upon-installation self destruction of an NOS JAN 6146B recently purchased from a well known supplier in Nebraska. He refused to honor an exchange, claiming that the tube was tested before shipment and therefore simplycould not be bad. Another identical example is working perfectly in the rig -- a TS-830S.

Topic: 49876 Message: 49879

Cid,
Craig is correct regarding the "MP." A "matched pair" is not necessary, required, or needed in our KW hybrids...it's a wast of you $$.
I also have had bad and good luck with some "not made in the USA tubes." I do tend to gravitate to the made in the USA versions.
Unless the seller has "high-potted" and tested further after that, any tube my not function in the real RF environment. A basic tubes tester is just that. You can ask just about anyone here...let's say..seller sez: Tested 110 out of possible 130 on my golly gee-whiz tube tester." You buy the tube..and it just doesn't work in the real world...the 12by7a driver tube and the 6146's are just 2 examples. Test them in the real world RF operating environment...in your rig. Then find and test another driver and a set of finals to keep around the shack. You'll just have to remember to rotate the tubes around every so often.
 Another good thing to have around when getting new final tubes...is a supply of the correct cathode resistors...'cause if the tube(s) arc over...it will take out the cathode resistors, or you can install the "arc protection" mod.
If a seller fails to honor a return/exchange...don't do business with them anymore...I know.... sometimes easier said than done.

49882. Hybrid Net Update (October 19, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-19 22:58:37 UTC
From: Mark Gilger
Topic: 49882 Message: 49882

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There were 16 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
3 running TS-830S
0 running TS-511
1 running 599 twins

I was running my TS-940S & Drake L4B amplifier.

The Sunday net was run by Jimmy, WB2KNR. There were 10 stations checking in under fair band conditions. He had the following number of radios checking in. There were 3 new first time check-ins: K9 ILL BUDDY, KB8WDX WALT, W1GKB JOHN.

3 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running maTS-520.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 82, Sunday□s total = 73
April 2014, Saturday□s net total = 64, Sunday□s total =43
May 2014, Saturday□s net total = 66, Sunday□s total = 35
June 2014, Saturday□s net total = 43, Sunday□s total = 59
July 2014, Saturday□s net total = 24, Sunday□s total = 46
August 2014, Saturday□s net total = 62, Sunday□s total = 53
September 2014, Saturday's net total = 49, Sunday's total = 27
October 2014, Saturday's net total = 49, Sunday's total = 41 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

49884. Build a DK-520 for the TS-520

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-20 05:32:49 UTC
From: junkmailsux@...
Topic: 49884 Message: 49884

Hi guys,

Has anyone tried to build a DK-520? By the schematic, it doesn't appear to be too difficult. I didn't see anything but cap's, resisters & diodes. I know it's a bit over my head but I might have a friend that would donate some time for me.

Just a thought.

Please keep in mind that my brain is Swiss cheese from the amount of pain meds that I've taken over 13 years so, please, no condescending remarks this time.

Topic: 49885 Message: 49885

The 8 pin DIN plugs that fit the TS series VFO cables are hard to find I believe. I've just ordered and received 4 from Farnell - they are part code 809-792 and look identical. I hope this is useful.

Simon, M5POO, Corbridge

Topic: 49885 Message: 49886

Simon and others,

The VFO 8 pin DIN VFO socket you are referring to applies only to the
TS-530 and TS-830, not all TS series KW hybrids.

The TS-520 and TS-820 rear panel Remote VFO socket is a 9 pin "Tube"
socket not a DIN socket.

The TS-520 and TS-820 rear panel 8 pin "Octal" socket is the "REMOTE"
socket and the connections are as follows:

Pin 1 is ground
Pin 2 not used
Pin 3 N.C. relay contact (N.C. stands for Normally Closed)
pin 4 is ground
Pin 5 is N.O. relay contact (N.O. stands for Normally Open)
Pin 6 is remote ALC input (labeled ALC FEEDBACK in the manual)
Pin 7 is note used
Pin 8 is External Speaker

Not hard to build but you need to take another look. You missed the heart of it which is an active device.

Need a transistor configured in Emitter Follower (buffer) for the Het Osc signal. Go to N6WK website where you can find the manual and good installation pictures for the DK-520 perfboard which contains the buffer amp which is mounted close to the RF board. Also will need couple of simple resistor divider networks to reduce the Carrier and VFO signal levels down to approx 300mv rms level to drive the DG-5.

If you cant find the 2SC460(B) might try a 2N3904. Someone else may have a better device.

If you dont already have a DG-5 unit I would recommend building the Arduino emulator which was recently discussed here. The DG-5 is not without its soldering and plated thru holes problems.

Guess which one I'll go with. The 2SC460(B) is around $7.50 for 1. The 2N3904 is $1.35 for 100 of 'em. LOL

Thanks! I did see that, I just forgot to mention it.

Todd's Arduino emulator is what got me hooked on this idea. I can't afford the DG-5 even at $35 but maybe someday. :D

Sid,

What you will need to do is follow the green wire back to it's next connection point\board then cross reference that back to the schematic diagram to see where it actually connects. This is an area that you dont want to make mistakes with

If the GREEN wire is hanging lose, I suspect both 6146 filaments do NOT light up BUT the driver tube filament does light up!!

Turn the 830 upside with the bottom cover removed.

Looking at the final unit's PC board, you will notice a "YELLOW" wire connected to a small square pad labeled "IPM". "IPM" is short for "IP Meter".

Next to the IPM pad you will see a large square pad that connects to a "Y" shape foil run. The large square pad is pin 1 of V1 6146 (front final tube). The "Y" shape foil run connects pin 1 to pin 4 and pin 6. You will see the same on V2 (rear 6146 tube socket).

Pin 4 is the 6146 Beam Forming Element and pin 6 is the other side of the cathode. The "Y" shape foil connects the Beam forming element to the cathode, even though the Beam forming element is connected inside the tube back to the cathode.

The GREEN wire is soldered to pin 2 of V1. The GREEN wire, if you measure it with your AC volt meter before connecting, it will have 12VAC on it. This is applied to the "series connected 6146 filaments" to provide filament voltage for the final tubes.

You can see all this by going to my website and downloading the pdf file showing the final unit Pc board bottom view

Terry, and the group,

The conversation on the DK-520 caught my eye, but my question is:

Can you use this with a plain vanilla TS-520 (as I have) or does it work only on the TS-520S?

I've seen discussions about the DG-5 in many places, and those seem only mentioned along with the TS-520S, so I need the clarification before sending my e-mail to Santa Claus.

Thanks!

John,

The DK-520 is designed to be used with the TS-520 which does not have
the rear panel CAR/VFO/HET output sockets.

The DK-520 will not work with nor is it required nor design to be used
with the TS-520S and TS-520SE since they both already have the
CAR/VFO/HET output sockets on the rear panel.

You can download the DK-520 manual from my website

www.w5rkl.com

When the page comes up, click on Manuals, Docs, and Mods link at the top
of the page. When that page comes up scroll down to the "TS-520" and
click on link #3. This link contains the installation instructions and
the service manual in on pdf file.

If you have A/C power line current on your mic, then there is also A/C power line current on the rig's chassis, and that problem needs to be fixed right away because it's a safety problem.

In any case, a hot mic is almost always caused by RF currents on the mic, and three-prong grounding the rig won't eliminate those currents.

I think that it's good safety practice to ground the rig's chassis. I didn't modify or change out the rig's original power cord to do this. Instead, I ran a separate ground wire from the wingnut ground bolt to the A/C power ground at a nearby electric outlet. I took a spare A/C power cord, removed the hot and neutral prongs to do this. Just to be clear – this is not an RF ground – it is a 120 VAC power safety ground.

If the "bite" occurs in transmit only when speaking into the microphone then the problem is caused by the power transformer's AC filter caps to ground but rather caused by RF in the shack.

Attic antennas can cause high RF in the shack which will cause distortion in the transmit audio and RF bites on the microphone.

If the primary AC filter caps are bad, the operator will experience the bite whether in transmit or receive.

Steve,
It's time to perform this upgrade designed by Terry, K9TW.

I had a problem several years ago with my TS-520S that it kept
blowing resistors up even after putting new tubes in. This fixed the
problems and I have not had a problem since performing this modification.

If the final tube cathode resistance is infinity after you replaced the cathode resistors then in transmit the only current path is through the IP meter circuit which will cause the IP meter to peg fully to the right.

I recommend you check the cathode resistance, pin 1 to ground (either final tube socket pin 1 will do). The resistance should be approximately 5 ohms.

If the tube(s) arced then the arc can easily result in 900VDC appearing on the final tube cathode, pin 1. This is caused by the arc occurring between the plate and beam forming element, closest element to the plate. The Beam Forming element is connected to the cathode on the Final Unit's PC board. Therefore, when the arc occurs, the plate voltage appears on the Beam Forming element which also allows the plate voltage to appear on the cathode circuit. If the meter switch is set to IP when the arc occurs, the voltage and current levels flowing in the IP meter circuit are excessive and can easily damage the meter.

Below I have provide you with the damage that can easily occur when an arc occurs in the final tubes.

When you consider 900VDC on the cathode and a cathode resistance of 5 ohms due to an arc in the tube, it doesn't matter which one and it only takes 1 tube to arc for this to happen, what do you think would be the final tube cathode current? You can easily determine the answer to that question by using simple Ohms Law formula:

I = E / R

or

900 / 5 = 180

That's "180 amps" NOT "180ma" flowing in the cathode circuit!!

Considering that all 4 of the 20 ohm cathode resistors are 1/2 a watt each for a total cathode resistance of 5 ohms at "2 watts" and with 180 amps flowing though 5 ohms of cathode resistance, what do you think would be the "power dissipated" in the cathode circuit? You can figure that out rather easily too using the following formula:

P = Isqrd x R

or

180 x = x 5 = 162000

That's "162,000 watts". Divide that number by 4 and you will find that each 1/2 watt 20 ohm cathode resistor will dissipate 40,500 watts each.

What do you think would happen to those four 20 ohm 1/2 watt cathode resistors with each resistor attempting to dissipate 40,500 watts of heat a piece? They would be destroyed and the fuse in the 830 would more than likely blow!!

Why did you replace the 6146Bs with 6883B? What did you expect to achieve, more power out?

He explained this in a follow-up. Not more power out at all. More money in. Pocket. 6146's have caught the eye of the scumbags on the internet who corner supplies and run up prices. 6883's aren't on anyone's radar yet for profiteering and they are still a few bucks each. Apparently the major difference is the filament wiring, and they are otherwise equivalent replacements for the standard 6146 normally seen.

(I can easily understand this motivation. Some of us just can't afford six full rigs in the shack, all running, with ten or a couple dozen more, unused for umpteen years though still in perfect working order, in boxes in the attic/basement. And novice Hams doing without or stuck with some Baofeng VHF/UHF handheld as the sum total of the gear in their "shack.")

I also need one other part. In another thread on this group, it's said to be available at Kenwood.

40-4711-03 470UH FERRI-INDUCTOR $1.23
http://www.kenwoodparts.com http://www.kenwoodparts.com

The 98 results I can narrow it down to skip right over that part number.

I also thought I had found it at PacParts for under $2 but it's discontinued there.
http://www.pacparts.com/part.cfm?part_no=L40-4711-03&mfg=Kenwood
http://www.pacparts.com/part.cfm?part_no=L40-4711-03&mfg=Kenwood
Is this just a wire wrapped ferrite? Does anyone have a pic or spec's?

Thanks
Chad

Hi Chad,

Don't worry so much about the brand name just find anything that's
470uH. At that value it is probably a bit bigger than a half watt
resistor. I don't know much about component suppliers in the US but I
imagine you could get them at most hobby outlets.

Try Mouser part No 542-78F471-RC

I made a board for the DK-520 using something similar.

I could have missed it but I don't think he said where he got the 6883Bs. He did say he had more coming when he attends the Georgetown Ohio ham fest.

I stopped buying vacuum tubes at ham fest a number of years ago. I buy all my tubes from vacuumtubes.net. The 6146As in my HW-101, SB-400, SB-401, and SB-100 were all purchased from vacuumtubes.net 4 years ago and they are still producing full output.

I would recommend he purchase the 6883Bs from a reliable vendor that guarantees the tubes. The online tube store I use, vacuumtubes.net, sell 6883Bs for $16 each and they guarantee their tubes for 30 days.

www.vacuumtubes.net

I agree, there are sellers who are selling 6146B "Matched pairs" for high prices but the final amplifier in the KW hybrid doesn't require matched pair of 6146Bs.

Also, if operators tune up to full output and if they operate CW, lower the power to about 85 watts and don't push the audio for higher power output on sideband, the final tubes would last a lot longer. Also, don't stack other ham gear along each side and on top of the KW hybrid. I see a lot of station pictures showing the transceiver on the bottom and in the middle with other ham gear stacked along each side and on top. I wonder how long it's going to take before that transceiver overheats and fails???

Sid: Suggestion>>>
Have you checked the voltages at the screen grid (SG) and all the other voltages on the final board?
Ohms from cathode to ground also. (already mentioned to be 5 ohms)
Compare these voltages to the Manual.
You can do this without the tubes in the unit.
Maybe this will help find the problem.
Please let us know.

I just purchased a mint Heathkit HX-10 Marauder (2x6146B). This thing is built like a battleship, so the plan here is to use it as the transmitter for digital modes (and maybe some AM) while using the TS-830 as the receiver. I want to keep some strain off the Kenwood power transformer and output stages.

The question I have, running about 70-90 watts out, is shorting TS-830 antenna jack to ground enough protection? If not, any recommendations would be appreciated. Both rigs have their full metal cabinets, all antenna runs are coax. Rigs will be grounded together.

Thanks,

Bob WA2JAJ/4

Hmmm. Running digital modes at full output will be detrimental to any transmitter regardless of the threat to your non-isolated receiver's front end. All you need is about 30 or 40 watts output on digital at most. Running full bore will blow your finals and give your listeners a distorted signal (briefly).

Congrats on the beautiful old machine from Benton Harbor, though.

Bob,

Running 70 to 90 watts out with the Marauder is okay on CW and sideband but it's NOT okay for AM!! AM power should be kept to no more than 100ma or 25 watts carrier. The Marauder's AM is in "LSB" ONLY and it's NOT plate modulated AM.

If you are running digital modes then I recommend you keep power output down to between 20 and 30 watts.

The weak link in the Marauder is the power transformer!! There are hundreds of Marauder HX-10s out there with blown power transformers. Some hams have changed the power supplies to solid state power supplies, thinking that will help keep the heat in the power transformer down. Not true plus the 5R4GY rectifier tubes have a voltage drop across the tubes that is higher than the .7VDC a solid state diode has. If you solid state the power supplies, the result in a much higher DC voltage applied to the circuits which can easily cause problems and/or damage components.

I have a Marauder HX-10. I run it on CW most of the time using an SB-303 solid state receiver through a simple 120VAC DPDT relay for antenna switching and receiver muting.

If you do not have the full manual for the Marauder I highly recommend you spend the money and buy one!!! You also should ensure the traps are adjusted properly (see the manual for details).

The original final amplifier cooling fan is, in my opinion, insufficient to keep the final amplifier cool. I removed the one in my Marauder, made a new cover out of perforated aluminum found at hardware stores, and mounted a 120VAC muffin fan on top, blowing air down into the final cage. Yes I've been told that blowing air into the amplifier will result in dust build up. I have NOT experienced this problem plus I keep the final amplifier cleaned every so often so dust doesn't build up.

I'm sure you have notice the weight of the Marauder, approximately 85 pounds. You will need a desk to support at least 150 pounds to ensure the other gear sitting next to the Marauder doesn't cause the desk to collapse. I built a simple desk out of 5/8" plywood and 2x4s. Cost to build the desk, about $15 depending on the cost of the plywood. The desk will hold up to 350 pounds without any problem.

I agree Craig. The final amplifier in the Marauder HX-10 is NOT designed for full continuous RF output.

Bob,

Just because a transmitter has a fan doesn't mean it can withstand full RF output such as AM, digital modes such as PSK, AMTOR, and FSK modes on a continuous basis. While the transmitter has FSK and AM modes, the power supply and final amplifier are not designed for continuous full RF output using those Modes!

The Marauder's FSK mode is actually true "Frequency Shift Keying" which mean the rear panel' "FSK" socket, when connected to a switching keyboard or RTTY keying circuit, actually shifts the Marauder's "RF Carrier" between Mark and Space, not some sound card Audio Frequency Shift Keying (AFSK) audio tones.

If you are going to use the TS-830 as a companion receiver to the Marauder HX-10 transmitter, I don't recommend that. There are plenty of other receivers that would be a better choice. Drake R4A, R4B, the Heathkit SB-300, SB-301, SB-303 and the Kenwood R599 are just a few examples of separate receivers that would work well with the Marauder. You will need a antenna switch and receiver muting relay circuit regardless of the receiver you use. You will need an enclosure to house the switching and muting relay along with the 3 SO-239s you will need to connect the receiver, transmitter, and antenna together.

By the way, the Marauder HX-10 works best with "6146As" not "6146Bs". You can purchase 6146As from the following link

www.vacuumtubes.net

for $22 each. You will have a difficult time neutralizing the Marauder if you use 6146Bs. I run 6146As in my Marauder and they work very well.

You should take the time and read the manual then perform a check of the transmitter's alignment. If the current alignment state of the transmitter requires adjustments, follow the instructions in the manual. A word of caution. Do NOT disconnect the final tube plate voltage then leave the final tube screen voltage applied then switch to transmit. The screens of the final tubes now become the plate and excessive screen current will flow in the screen circuit destroying the final tubes. The normal screen current in a 6146 is 12.5ma and this maximum level can easily be exceeded if you disconnect the final tube plate voltage but leave the screen voltage applied to the tubes in transmit!!

Sid

If I were you I would pull the Final tubes and then measure the Cut Off bias voltage in Rx mode and the Operating bias voltage in Tx mode at the tube socket control grid pin 5 on the final board. Run the bias pot thru its range and make sure you have good smooth control of the Operating bias voltage. Make sure the anode caps and parasitic suppressors are not touching anything in the PA cage as will be energized at 900vdc.

Mike is correct that typical arc over occurs from Anode to Cathode (beam forming plates) violently blowing the cathode meter shunt resistors, but you can also experience more rarely arc over from Anode to Screen Grid and to the Control grid. I have had 2 or 3 TS-830s come across bench with significant damage to the FG line and associated components all the way back to -C supply. If it arcs to the Control grid heavy current will take path on the FG line back to the Audio board. It may burn up the Bias Voltage adjust pot on its way back to -C supply return.

After you replace the four 20 ohm meter shunt resistors and with no finals tubes in the sockets suggest you verify proper cutoff bias and operating bias voltage at Pin 5. I would also clean the bias voltage adjust pot and set the voltage at Pin 5 to approx -60vdc in Tx mode.

There are two common ways to hurt final tubes. One is anode arc over and other is thermal runaway due to loss of bias voltage. You say you cant set the zero signal plate current and it pegs out. That is not a problem with screen grid voltage. I would look closely at bias voltage.

Lou: Thanks for your reply. I found a PS-30 in a scrap sale and unloaded voltage was close to 14.6 VDC. It would not adjust to 13.6 as I thought it should. I finally noticed in the manual that unloaded VDC was normal under 16 and would come down when a load was applied.

Your figures follow what mine is doling and I thank you for taking the measurements.

Joe,

More information please? What do you read and why are you concerned?

Mine reads 14.2V at the radio with radio off dropping to 14.0V with radio on and 13.3V with 100W carrier.

Topic: 49920 Message: 49930

Many thanks to all responders. Having run the TS-830 with digital and RTTY, I am aware of the power limits of the 6146's. I plead temporary senility on that one. As for the TS-830 for the receiver for the Marauder, the points are very valid and I will now probably use my in-storage Hammarlund HQ-170a instead.

Have Marauder manual, and, rig was purchased from a "restorer" so hopefully alignment, neutralization, etc., will check out ok.

I will look to see whether the 6146s are "A" or "B"

I was hoping to save the space, and use the more stable TS-830 receiver, but I do have somewhere a digital readout for the Hammarlund. and maybe I can find some mods to improve the stability. Marauder, like Hallicrafters SX-101, leaves the VFO filament on when plugged in.

Again, thanks to all

Bob WA2JAJ/4

Just wondering if there would be any interest in my TS-530s before I put
it on a popular auction site?
Having had prices to repair/service the radio, I thinking of getting a
more modern radio instead.
The radio is not without its issues. RX fine, but no TX ☐ No Mic, band
selector out of sync with Plate selector.
Valves have been checked/replaced with known good ones and swapped back
and no joy in TXing.

Located UK .

Cheers

Date: 2014-10-29 21:09:47 UTC
From: k7mks@...
Topic: 49938 Message: 49938

A local ham has a TS-530 w/ an interesting problem with low power output of 40-50 or so and no ALC meter reading when the band switch is on 28 and yet everything seems to be OK when the bandswitch is set to 24.5 and 29. Gently moving the BS a bit, while on 28, has no effect on the PO or zero ALC meter reading. I can get an ALC reading by very slight rotation of the Plate tuning but PO remains essentially the same at 40-50. The finals do need to have neutralization touched up.

I am beginning to suspect the 28 position on the BS may have a defective switch contact on one or more switch wafers when 28 is selected. Comments will be greatly appreciated.

joe k7mks

the finals do need to have neutralization toucvhjed up.

Joe,

Sounds like the band switch wafer may be slightly loose, most common problem wafer to the last one closest to the final tank. Using very good light have a look at this wafer and as you turn band switch through range watch and see if the fingers move, this could indicate bad rivet. However, the other issue is has the radio been modified for 11m? Report back and we can go forward

Here is a copy of the instructions to convert a 530 to CB Band.
Should be easy to reverse.
Sorry I do not have the pics, however they are available somewhere probably in CB Tricks>>>>
ten four, good buddy, see you on 32 down...
Wally KC9INK

This simple modification changes the 29Mhz band to give you full operation in the 27Mhz band. The band selector will be set to 29 and the +0.5 switch will be off or on to give 27 or 27.5 MHz. The display will correctly read the frequency on the 27Mhz band.

Remove the top cover. Locate the counter pcb (centre front). We will modify the diode matrix to give new BCD PLL divider codes and BCD display codes to give us the 27Mhz band. There is no need to remove the pcb as all the work can be carried out on the component side with the board in situ.

Cut the cathode of D26 or remove D26 entirely.
Take 2 IN4148 diodes and twist their cathodes together and solder. Trim this twisted end and solder on to the pcb where D26 cathode was connected. We will refer to these two new diodes as D901 and D902.

Take a short piece of hookup wire and connect to the anode of D901, using a rubber sleeve to insulate the connection. Connect the other end of the wire to the anode of D49.

Now trim the leg of D902 slightly, bend it over and down and solder it to the anode of D25.

Next Cut D35 and D34 cathodes, leaving enough wire on the diodes cathodes to solder to. The two diodes are side by side. Take a piece of hookup wire and remove enough insulation so that you can solder it to both D34 and D35 at once, bridging the cathodes together. Connect the other end of the wire to the cathode of D50.

The RF board coils for the 28/29 bands may need slight adjusting, these are L12,L21 and L31. This step is optional and may make the radio perform slightly better on 27Mhz. I did not do any tweaking myself and was able to get 120W on 27.500. RX sensitivity did not seem to be affected by the mod.

Mark, could be the Indicator digit driver Q11 or the resistor block RB3 that connects it to the readout tube. Possibly that digit is not being "turned on".
If you have a scope you should see a square wave blip on each of the driver's output pins 10--15.
You should see the same blip at the resistor and then the tube assembly.
Hopefully the problem is not in the readout tube.
Please look at the schematic and circuit explanation in the service manual.
If you do not have a scope, try resoldering the connections on the board and measuring the respective resistor in the RB3 resistor block.Maybe you will get lucky and its just bad solder joint or one bad resistor.

Joe,

I mean no disrespect but "Shooting in the dark" is the same as "guessing". Loss of ALC is not always an indication of an 11 meter modification. Loss of ALC can be caused by the Rectifier Unit's R15 (56K 1/2W) resistor used in TUNE model which would be evident on all bands not just one band. A weak driver tube can also result in loss of ALC. Loss of ALC is typically not caused by weak final tubes or the rear panel's SG switch being placed in the OFF position.

I never inferred that a CB mod had been done. I was merely seeking comments of what to look for in case a mod had been done.

The unit has ALC and 90-100W PO on all bands except 28 which is the only band with no ALC and low power output so whatever is causing the problem is doing it on the this band only. If I had measurable ALC then power output should increase over the 150 ma Ip which I'm seeing for that band.

The 28 driver plate coil peaks nicely and I've eliminated that as the cause. I'm beginning to think that there may be a loose or cold solder joint on the 28 position of the bandswitch. Later today I plan to take a RF probe and try to locate where RF is low on 28 and OK on the two adjacent bands.

No disrespect was taken - I appreciated your comments.

Are you saying with the rig in CW mode and the Screen Grid switch off you can peak the ALC reading with the 10 meter drive coil (orange)? What is your definition of "nicely"? Where do you have to set the CAR Level pot? Where does the ALC indication deflect to?

If you have good ALC indication when peaking the Drive coil on 28 mhz bandswitch position then you cant have a bad rivet connection on the S1-6 wafer. The fact that you can get a good peak tells you that the parallel resonant tuned circuit that is being switched in between the Driver tube plate and the 6146 control grids is being seen electrically as evidenced by peak in RF voltage. This is what the tuned circuit does for you. It gives you maximum RF voltage swing at control grids of finals. My definition of good is RF voltage greater than 46 volts with the Car Level pot no greater than 1200 position. Also, the ALC indication should hold and not slowly drift lower during key down. You may not be able to get full scale meter deflection but should be able to get close to 3/4 scale. I am talking about the meter range and not the black printed ALC scale that means nothing unless you are modulating the rig. On all other bands should get full scale deflection with Car Level pot no more than #3 to #4 position.

Using RF probe or O-scope and running the TX Level Diagram is best and fastest way to troubleshoot low RF drive and/or low RF output.

You will need a 3 diode probe to measure RF drive voltage at the plate of the Driver Tube or the DRV terminal on the Final board or Pin 5 of the 6146 finals. A single diode probe is only good for approx 30 rms rf volts. Above that you will burn out the diode.

Assuming you have the zero signal plate current set to 60ma then you will have approx -65vdc operating bias voltage on the 6146 control grids. This means that to get the grid to go positive with respect to the cathode you will need to overcome this DC offset below the zero axis. You need the grid to go positive with respect to the cathode in order to have grid current which in turn will result in ALC action which will reduce the ALC bus voltage and drive the ALC meter indication up scale. For that to occur you need no less than approx 47 rms rf volts at finals control grid. 47 x 1.414= 66.5 peak rf volts. This means control grid will be approx 1.5 volts positive with respect to cathode. Anything less than approx 47 rms rf volts means NO ALC indication. You will still have RF output power just no ALC indication.

Just a shot in the dark.
I've got a Kenwood TS-520 that was given to me for a website design. Unfortunately, some yutz tried to change it to 11M and I think they screwed it up. The radio won't tune on any of the 10M sections. The 37.995MHz crystal is missing but I can't afford $30 for a crystal so I thought I'd ask if anyone had one that they didn't need. Fingers are crossed but I'm not holding my breath. LOL

Chad,

Have you checked the other two 10 meter HET OSC crystals to ensure they are the correct ham band 10 meter crystals?

28 = 36.895Mhz
28.5 = 37.395Mhz

The 37.995Mhz HET OSC crystal is for 29.1Mhz.

Write Bob Mansker, KE5FTF, an email, ke5ftf at mail dot com, he may have the crystals.

There may be other mods that were done that you have not found. I recommend you perform a thorough check of the RF Unit HET OSC using the TS-520 service manual and schematic.

I forgot to mention at 28 mhz trying to run TX Level diagram your RF measuring device may de-tune the circuit. All probes and test leads have series inductance and shunt capacitance. Even a 2 or 3 pf probe can affect your reading.

Best to not use alligator or mini-grabber test leads at this frequency. Just touch your RF or O-scope probe tip directly on measuring point. If looking at RF drive on Pin 5 of 6146 tube socket carefully touch probe tip there and make sure it doesnt slip off and make sure the ground lead is securely clipped and doesnt slip off and swing into the 900vdc filter caps or the HV rectifier board which is always hot.

Assuming proper alignment the Marker should peak close to 1200 on 28.8mhz. When you apply your probe should have to open the plates (turn Drive control CW) a few degrees to peak your measured RF drive voltage reading.

Again if you dont have a 3 diode probe pretty easy to make one or watch Ebay for a Heath PK-3 and when you get it open it up and make sure the builder actually installed 3 diodes in it.

If reading is low run Car Level pot full CW position. You can also peak the 28 mhz Drive coil and the Mixer coil for maximum RF voltage at this time. Ordinarily should not use Mixer coil to peak Drive but receiver has plenty of gain so if your drive is marginal it is OK to get a little more drive by peaking the Mixer coil as well as the Drive coil. You do this at some expense to the receiver, but a lot of owners and techs use this method to get some additional ALC indication.

Topic: 49958 Message: 49958

Greetingse :
This is my first post.I have a TS830S which I have no problems with when I attach the Bencher straight key in the back of the TS830S to operate cw.In addition I have a Palstar CW50A keyer with which I practice cw with my recently refurbished K8RA paddle . The problem arises when I try to connect a line between the
" cathode keying " plug on the back of the keyer and run it with the usual 1/4" plug to the key jack in the back of the TS-830S.As soon as I either turn on the keyer or just connect the keyer and the 830 it gives me a key down sound, as if it were either tuning or transmitting.Turning the tune button on/off on the keyer or switching to send/receive on the 830 makes no difference.I blew a fuse yesterday before I could get the plate current down or turn the rig off.Is it possible that my radio guy, who is Thai, miswired the cable.What are the connections supposed to be anyway, between the CW50A keyer and the 830. This is driving me nuts and I find it hard to operate.I had a stroke last year and operating now with a straight key is really tiring.Does anyone have any ideas.Not being a wrench I imagine it is probably the wiring but my radio guy just changed it.
Yours Truly
Richard
HS0ZFQ I hope I used the correct format.

Richard,

The TS-830 does not use Cathode" CW keying, the TS-830 uses "Grid Block" CW keying. Therefore, connect the CW50A's "Grid Block" socket to the TS-830 rear panel CW key socket.

Chad,
I agree with Mike-w5rkl. Check the other crystals for proper frequency markings. The "CB hack" that is done to the 520(s) is the most difficult to do and undo due to the construction of the rig.
  You can go to the groups home page, and look/search under "photos" for the "TS 520 OSC BOARD CB HACK" uploaded by yours truly, to see what to look for. Sometimes, having a small dental type mirror to get down between the board(s) is a great help as is, a really bright flashlight

Mike W5RKL
Grid Block Keying is right.
Measure 69 volts here on my TS-830 .

Reminds me of the Grid Block Keying I used on my old ARC-5,
way back in the 50's as K4KKQ, 21 years old.
On my old Bug,
Had to put a leather patch over the screw holding the thumb pad.
It would bite like crazy when I put my bare feet on the concrete floor.
That was when I was 21, now I always wear shoes.
But, my 1940 Bug still has that leather patch on it !

Good forum, and lots of experts helping out.

From: W5RKL
Topic: 49958 Message: 49963

Glen,

The TS-830, as well as the other KW hybrids and many other transceivers that used grid block CW keying, all have a "negative" grid block keying voltage of between -60VDC to -65VDC or so. Notice the "minus" sign to the left of the voltage values.

Cathode keying voltage, on the other hand, is a positive voltage and can be as high at +100VDC or higher, depending on the stage being keyed.

Grid Block voltage is used to bias a stage to cut off. When the key is closed (pressed), the grid block voltage is shorted to ground causing the negative cut off voltage to become "less negative", allowing the stage(s) to turn ON. Releasing the key causes the grid block voltage to increase (become more negative), turning the stage(s) to turn OFF.

Cathode keying simply uses the CW key as a "switch" to complete the cathode circuit of the keyed stage(s) to ground, turning the keyed stage(s) ON. Releasing the CW key causes the keyed stages cathode circuit to become "open", turning the keyed stages OFF.

Mike: Your explanation of the difference between cathode and grid block keying was exactly what I was going to ask you. I have committed the text longhand to my hardbound notebook. This is Richard HS0ZFQ and when you told me the TS-830S was grid block voltage keying I was astounded.Anyway I switched the cable from cathode keying to grid block keying and that solved part of the problem but I blew another fuse. I am back to using my Bencher hand key with no keyer until I get a new rig. So now when I begin tuning up I check my bias in SSB mode 60Ma.Next I go to TUNE and peak the ALC reading and then dip the plate and peak the rf. Now for the weird part.When I turn the mode switch to cw to complete the tune up I do not get any output unless I turn the standby switch to send.This had happened once before. So if I remember correctly between transmitting and receiving now I have to flip the standby switch from send to receive. Something is rotten in the state of Denmark

Richard,
What you describe having to use the send switch when in "CW" mode is normal. See Pg 20 (5) CW OPERATION of the TS-830S Instruction Manual.
To avoid having to flip the send switch all the time...set your VOX gain control to "ON"...and also set your delay time with the VOX delay control. Mine's set to delay about 1 second.

Blowing fuses needs to be further checked out

49967. Hybrid Net Update (November 2, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-02 19:35:59 UTC
From: Mark Gilger
Topic: 49967 Message: 49967

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There
were 16 stations checking in under good band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
4 running TS-530(x)
4 running TS-820(x)
1 running TS-830S
0 running TS-511
0 running 599 twins

I was running my TS-830S & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
19 stations checking in under fair band
conditions. He had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
4 running TS-830S
1 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S & Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85

Neil,
A few words of advice: The TV-502 & TV-506 require unique plugs that are getting very difficult to find. The SM-220 will function with the rig in question but, if it has a pre-installed 'pan display" make sure it is the BS-5 which has the 3.395Mhz IF, the BS-8 will not work with the 520(s)
  Cheers.....

Neil,

I would concur with Joe. The SM-220 is normally found w/o a BS-5 or BS-8, or with a BS-8. Kenwood did not sell many BS-5 units for use with the TS-520(S). Thankfully, when I purchased my SM-220 in the late '70s, I purchased the BS-5 a couple weeks later. And, no, it's not for sale... Hi.

Be very careful, as the BS-8 designed for use with the TS-820(S) initially, will not work with the 520 series as Joe stated.

I never was able to get over 80 W from my TS520 on 10M and I got it new out of the box.
Got 100W out on all the other bands with 200mA plate current.
I believe it was a design weakness.

My radio is Ham Radio...CW is Real Radio

I forgot to mention at 28 mhz trying to run TX Level diagram your RF measuring device may de-tune the circuit. All probes and test leads have series inductance and shunt capacitance. Even a 2 or 3 pf probe can affect your reading.

Best to not use alligator or mini-grabber test leads at this frequency. Just touch your RF or O-scope probe tip directly on measuring point. If looking at RF drive on Pin 5 of 6146 tube socket carefully touch probe tip there and make sure it doesnt slip off and make sure the ground lead is securely clipped and doesnt slip off and swing into the 900vdc filter caps or the HV rectifier board which is always hot.

Assuming proper alignment the Marker should peak close to 1200 on 28.8mhz. When you apply your probe should have to open the plates (turn Drive control CW) a few degrees to peak your measured RF drive voltage reading.

Again if you dont have a 3 diode probe pretty easy to make one or watch Ebay for a Heath PK-3 and when you get it open it up and make sure the builder actually installed 3 diodes in it.

If reading is low run Car Level pot full CW position. You can also peak the 28 mhz Drive coil and the Mixer coil for maximum RF voltage at this time. Ordinarily should not use Mixer coil to peak Drive but receiver has plenty of gain so if your drive is marginal it is OK to get a little more drive by peaking the Mixer coil as well as the Drive coil. You do this at some expense to the receiver, but a lot of owners and techs use this method to get some additional ALC indication.

Good day, new member here. Glad to be on board.

I just acquired a new-looking ts-820 with user and service manual from the original owner.

It was taken out of service in the late 90's - the fellow lost interest, and he just passed it to me.

So, the rig lights up. There is a hiss out of the receiver.

The digital display does not work. There is no high voltage indication on the meter. Tuning manually against my good HF rig, the unit is not receiving at all. Not sure about TX as I have no mic, but using the front panel tx/rx switch, aside from the speaker hiss going silent, there is no change.

I'm thinking power supply issues since there is no HV or power (taking a guess here) to the digital display board and associated circuits.

Is this a common issue with these rigs?

And yes, I will do some reading on here. I'm only a member for the last 24 hours.

Thanks

Ian,

None of the meter switch positions are enabled in receive. The meter, in receive, display ONLY variations in the receiver's AGC voltage (S units). The meter switch is enabled ONLY in transmit. Therefore, setting the meter switch to any position in receive is useless.

Have you checked to ensure the jumper plug has been installed into the rear 9 pin remote VFO socket? This is shown in the operator's manual on page 8. If the plug is not plugged into the 9 pin remote VFO socket or a simple jumper wire is not between pins 8 and 9 on the 9 pin remote VFO socket then there will be no 9VDC power to the TS-820's internal VFO and the TS-820 will appear to be dead and the digital display will also be dark.

You said the operator and service manuals came with the TS-820. Have you spent time studying the operator's manual to learn how to operate the TS-820 and how to properly tune the TS-820's transmitter?

Ian,

The Kenwood TS-820/TS-820S is no where near the same or even remotely similar to a Yaesu FT-980!

You said you read about the plug but you didn't check it. That should have been a step you should have performed when studying the remote VFO plug in the operator's manual.

It is not a Kenwood "Design Weakness" to have slightly lower RF output on 10 meters.

It is very easily understood. All designers of multi-band transceivers have to play the hand they are dealt. Lower RF output power on 10 meters is not unique to the TS520 just as lower receiver gain on 10 meters is not unique. It is because you cannot have tuned circuits with optimum Q on all 5 bands due to the physical and electrical layout and the fixed values of parasitic capacitance and inductance that the Driver tube input and output presents along with the pc traces, lead wires, bandswitch contacts etc. Designers are forced to use practical values and physical size of inductors and capacitors that can be adjusted that in combination do not result in optimum LC ratios and optimum loaded Q. This especially manifests itself on 10 meters.

Do some parallel resonant calcs or build a 10 meter linear and you will understand what values you are dealing with. Selecting the tank capacitor to have a low enough minimum value has always been a challenge to those of us who could not afford a vacuum variable.

What it boils down to is because you are dealing with a multi-band transceiver. A single band radio can be better optimized on 10 meters, but still has limitations. A multi-band transceiver design results in fixed minimum levels of parasitic capacitance and inductance (in Driver tube , in wire leads, PC traces, bandswitches etc) that force the designers to use less than optimum LC ratios in the 10 meter parallel resonant circuits. If you look at Mixer and Driver tuned circuits you will see no parallel capacitors with the associated slug tuned coils. Why is that? The Driver tube input and output capacitance and the PC traces, lead wire etc present fixed parasitic capacitance that is used to resonate those coils. Designers have to live with less than optimum LC ratios.

If you were a multi-band transceiver design engineer where would you chose to make compromises in loaded Q? This is easy question to answer. Common sense would be at the high end of the multi-band transceiver coverage range. WHY? Because easy to use other means to compensate for it. Most commonly we employ high gain directive antennas on 10 meters to make up for the lower power output and receiver gain. Easy to make and swing 10 meter high gain directive antennas and not so easy to make 160 meter high gain rotatable antennas. So if you had to make a choice you would optimize the tuned circuit LC ratios on the low end of the transceiver band coverage.

Same problem with the early tube boat anchor receivers. They were nearly deaf on 10 meters by todays standards. This again was due to the fixed minimum values of circuit parasitic capacitance and inductance that forced the designers to select tuned circuits with less than optimum LC ratios which meant less than optimum loaded Q. Back then many of us built Nuvistor pre-amps to improve 10 meter receiver performance when those tubes became available and later when FETs and Mosfet came on the scene. We didnt say that the receiver had Design flaw or Design weakness. We understood why it performed the way it did and we compensated for it with antennas and later with external low noise high gain pre-amps.

So KW hybrid having slightly lower RF output on 10 meters and less receiver gain is not due to Design Weakness. It is due to Design Requirements that the physical size and layout of

electrical components and interconnecting paths present at 10 meters. As I say very easy to compensate for the slight performance difference this presents.

Besides the difference between 80 watts and 100 watts on 10 meters is meaningless when the band is open especially if you are swinging a 10 meter yagi. You can work the world easily with 80 watts.

Also, If I may add to Terry's statement, on 10 meters you are dealing with almost 2 MHz of band-with. On the rest of the bands you are only dealing with a few KHz of band-with. I don't care what Hybrid you are using, the tank coils are going to have a hard time covering that much frequency. If you align your coils according to the manual on 10 meters at the point you should come close to full output, but as you move away from that point, the power will gradually drop off. Both of my 830's and my 530 are the same way. I lose about 15 watts of output on each end of the band. My friends FT101e is the same way.

Most solid state rigs have tuners built into them that can compensate for this much band-with. Thus you can obtain full output. That is the nice thing about built in auto tuners. I don't know if auto tuners would be the right name as I would think "compensators" would be a better name. I have owned 3 different solid state rigs and got rid of all of them in exchange for the Kenwood's I now run. I will never get rid of these rigs. They are simple to use after you read the manual a couple of times. Great audio both ways and I get great reports on them.

From: va2ir@...
Topic: 49972 Message: 49979

Update: Getting home last night, I checked the back of the 820, and sure enough the 9 pin plug that jumpers the remove VFO was not there, but it was in the goody bag full of misc. connectors and plugs that came with the rig. So plugging in the round plug and with fingers crossed, I turned on the radio and it worked.

However, the digital display is wonky so it needs to be investigated. And the main tuning dial is off by about 9kc. However, dialling up my Ft980 on 14.250 and listening over the 820, the manual dial indicated just under 14.260.

So the rig does work. When I have more time, I will run thru the articles and postings regarding the display and cleaning the band switches etc. to get this rig in nice operating condition.

Best

Topic: 49940 Message: 49980

I wasnt talking about the Pi-Network (output tank circuit) efficiency. That is another similar subject. Yes bandwidth presents challenge. That is why KW gives you recommended frequencies on each band to perform the coil pack alignment. They want max RF voltage swing to occur at 1200 on the Drive Control when the VFO is at approx mid range. In this way you should be able to tune the Driver stage tank circuits to resonance at the extremes of the VFO travel. Might ask have you measured the RF drive voltage at 6146 control grids lock to lock? Might be interesting to do that on 80 and then on 10.

I was talking about the Driver stage and the band switched in tuned circuits between the output of the Transmit Mixer and the control grid of the 12BY7A driver tube and the tuned circuits between the Plate of the 12BY7A driver tube and the control grids of the 6146 finals.

Ideally the design engineers want to use optimum LC ratios for these interstage tuned circuits that result in maximum RF voltage swing and an operating Q that provides sufficient bandwidth without tuning being too touchy.

The main sources of this fixed parasitic capacitance that places constraints on the KW Designers includes:
1. The band switch contacts and associated PC traces.
2. The 12BY7A driver tube and the input capacitance from Control Grid to Cathode and the output capacitance from the Plate to the Cathode.
3. The 12BY7A tube socket and its associated PC traces.
4. PC traces and jumper wires on the Coil Pack and RF boards.

All of these sources result in something on order of 10pf to 15pf of fixed capacitance that will be in shunt with each band switched in slug tuned inductor (tank coil). We are not done yet. We have to be able to tune these mini tank circuits to resonance for each position of the VFO dial setting. We do that with VC-1, VC-2, VC-3 ganged Drive Control air variable capacitors. These capacitors are two gang with the Large gang presenting approx 5pf to 200pf and the Small gang presenting approx 5pf to 25pf of capacitance (on the lower end of this capacitance range as you turn the Drive Control cw and unmesh the plates at 29mhz for example).

So the Designers are forced at 10 meters to use a slug tuned inductor less than approx 1.0uhy (yes same for the pi-network tank coil). This results in lower than optimum LC ratio and lower than optimum RF voltage swing at control grids of the 6146 finals. As previously mentioned you wont see any fixed capacitors across the 10 meter inductors.

You can prove this if you have RF millivolt meter or O-scope. Load up on 80 meters and you will be able to open CAR Level pot at a low level (#2 to #3) and get full scale ALC indication and around 47rms RF volts at the control grids of the finals. You can do that at any setting of the VFO dial.

Now repeat that on 10 meters and you will have to open CAR Level pot much more (#5 or more) and may not get full scale ALC indication with exception of a well aligned TS-820,530,830. You will not see 47 RF volts at control grids of the finals. Maybe on order of 39 rf volts.

Probably beat this to death. All I was trying to do is respond to Mr. Davidsons comment that lower output power on 10 meters is due to KW hybrid "Design Flaw". I think more appropriately due to "Design Contraints" inherent in any band switched transceiver. Not unique to KW hybrids. Heath, Yaesu, Drake, and yes Collins Engineers had to deal with this fixed parasitic capacitance. As I stated in my original response easy to compensate for it by using high gain directive antennas on 10 meters.

I suggest anyone who enjoys this type of discussion continue it with me off the reflector and allow people to get back to discussing troubleshooting and repairing their Hybrids. I like trying to figure out how these treasures work and enjoy discussing it with those who have similar interests. I also have made extensive measurements like the capacitance values of VC-1 thru VC-3 that I can share if you need it and always interested in your measurements as well.

I am working on a (mostly) working TS-520S. When I go to begin tuning(Mode to Tune, meter to ALC, adjusting drive), the meter maxes out at the peak of the drive control. I have reduced the CAR control to minimum, and it does affect the reading, but the peak is still beyond the range of the meter(This is on 40m, my only current antenna). I will test other bands on the dummy load tonight. If I set the drive to the middle of the off-Scale reading, I can complete the tuning process, and the radio functions normally. At that point the CAR control accurately varies the key-down RF output(measured on my Bird). I am curious as to what may be causing the reading to go off-scale, any advice on how to proceed would be great.

The industrial engineer in me is starting to get very interested in the failure rate of the HV board R5/R6 meter limiting divider pair, seeing as we seem to be having a real run on this, "ALC is missing/really high when I go to tune mode but everything else works fine" thing.

And I know the yahooligan list thing is an absolute MESS to search through, but does anyone (besides me anyway) actually even try any more? I think it has been covered about a hundred times now.

John,

Sure you don’t want to keep it?

I have a TS830S that had similar issues after being stored for 25 years.

I installed a new band switch coupler from Ken K4EAA, used a can of DeOxIt Gold G5 to spray the band switch wafers 3 times over several days while working the band switch. Vast improvement. All bands working except 18 and 21MHz which are now intermittent. But I know I’m on the right track. Will keep working it for 100% reliability on all bands.

Will soon update the HV caps and install a final cage kit. That should hold my baby for many more years.

Total cost $65.

73

Tom

Just wondering if there would be any interest in my TS-530s before I put
it on a popular auction site?
Having had prices to repair/service the radio, I thinking of getting a
more modern radio instead.
The radio is not without its issues. RX fine, but no TX – No Mic, band
selector out of sync with Plate selector.
Valves have been checked/replaced with known good ones and swapped back
and no joy in TXing.

Located UK .

Cheers

John

The +265VDC is the normal "210" driver and final tube screen voltage No need to mess with that voltage.

An increase in R5 and R6 resistance from 56K to 64K, each resistor, will have very little affect on the final tube screen voltage with the MODE switch set to TUNE.

The normal final tube screen voltage with R5 and R6 at 56K each and the MODE switch set to TUNE with 265VDC applied to the HV Unit's 210 terminal will be

265 / 112000 = .00236 amps

.00236 x 56000 = +132.16VDC

265 - 132.16 = +132.84VDC

An increase of 16K ohms total (R5 and R5 in series) will result in a the following voltage change at the HV Unit's TUNE mode terminal with +265VDC applied to the HV Unit's 210 terminal:

265 / 128000 = .00207 amps

.00207 x 64000 = +132.48VDC

265 - 132.48 = +132.52VDC

As you can see there is less than a volt difference with a total 16K ohms of resistance increase.

From: lynn091@...
Topic: 49988 Message: 49988

Recently acquired a AT-200 and the front wafer switch on the band switch is broken. Anyone have a defective band switch that the front section is good?? Any thoughts as to a replacement wafer or switch??
Thanks
Lynn,kb5by

John,

The repairs for this radio are quite easy, just need patience. There are a number of people that can help you on this forum. We can even do it off list incase you are unsure of how to do things or need some finer guidance. I have just helped someone off list and they are very happy with the radio now. Things to consider are HV caps, definately band switch coupler and I'd consider the relay on the RF board. The maybe an alignment, with the right information you could get this baby up and running and enjoying working DX

Good luck with your decision

Subject: RE: [TS-520_820_530_830] TS-530s

John,

Sure you don’t want to keep it?

I have a TS830S that had similar issues after being stored for 25 years.
I installed a new band switch coupler from Ken K4EAA, used a can of DeOxIt Gold G5 to spray the band switch wafers 3 times over several days while working the band switch. Vast improvement. All bands working except 18 and 21MHz which are now intermittent. But I know I’m on the right track. Will keep working it for 100% reliability on all bands.

Will soon update the HV caps and install a final cage kit. That should hold my baby for many more years.

Total cost $65.

73

Tom

Just wondering if there would be any interest in my TS-530s before I put
it on a popular auction site?
Having had prices to repair/service the radio, I thinking of getting a
more modern radio instead.
The radio is not without its issues. RX fine, but no TX – No Mic, band
selector out of sync with Plate selector.
Valves have been checked/replaced with known good ones and swapped back

and no joy in TXing.

Located UK .

Cheers

John

I dont think it was a 520, more along the lines of a Drake\Swan or Heathkit. Our good friend Mike, W5RKL would be able to identify very quickly as he has worked on many of those radios. What epsiode and I'll see if we can identify

I dont know how you got off on Screen grid divider resistors or Screen grid voltage as the source of your "problem"? 210 is the name of the Screen Grid voltage source. Same with all HV power sources. It is the "nominal" screen grid voltage you would see key down on the 6146 screen grids depending on some variables including line voltage.

There is really no such thing as "too much RF drive"? This is not a Class C CW transmitter of the 50s.

You have to remember you are not setting a RF Drive Level. You are tuning two LC networks to resonance (Mixer and Drive coils on input and output of the 12BY7A Driver tube) and not setting RF drive to any meter indication level. You want maximum RF drive voltage swing at the 6146 control grids so that you can swing the grid positive with respect to the cathode and cause grid current to flow. When that happens you cause the ALC circuit to drive the ALC bus voltage down from RF-1 3.3vdc level to around 2vdc. The meter is monitoring the ALC bus voltage and when it sees this bus voltage go down it drives the meter up scale. You need to increase or decrease the CAR pot setting to keep the ALC indication at a point where you can see a peak in the reading as you adjust the Drive Control. You are not using the CAR pot to set a RF drive level.

If you are more comfortable keeping the ALC indication within top end of the Black printed ALC range on the meter face then simply reduce the CAR pot to put it there and then peak that indication with the Drive control. What you NEVER want to do is use the CAR pot to set a level. I have seen people on You Tube videos leaving the Drive Control at 1200 position regardless of the VFO setting and then flipping to Send and then setting the ALC indication to max of ALC black printed range with the CAR pot. That is wrong. You have not tuned the Mixer and Driver LC circuits to resonance if you do that. You have also detuned the receiver.

No one has asked you a clarifying question. When you say that the ALC indication pegs full scale in Tune Mode as you attempt to peak it do you mean the full scale deflection (FSD) of the panel meter or do you mean it goes outside the Black Printed ALC range on the meter face? If it is meter full scale then simply reduce the CAR pot and then peak the reading with the Drive Control. If it is outside the Black ALC range then dont worry about it. Simply peak the indication with the Drive Control. The Black range is there to facilitate modulating the radio in SSB mode so you dont splatter. Nothing more.

This step is very simple. Place meter in ALC, increase CAR pot to 1200, Flip to Send, Peak the meter indication (maximum) with the Drive Control. At anytime the ALC indication exceeds the FSD of the panel meter simply reduce the CAR pot to get meter back on scale so you can see the peak. If you have no indication of very low indication simply increase the CAR pot to give yourself something to work with.

You can test your Driver stage on each band by turning off the SG switch and peaking the Drive Control in CW mode. Should be able to get FSD on all bands with perhaps exception of 10 meters and indication should stay at FSD and not slowly fall off. A good rig this will occur with CAR pot below #5 or 1200.

Let the Driver tube rest between bands as it is running full bore in Class A and gets pretty warm doing this test.

Hi

After much consideration, I have sold the radio on to a new home. I did consider breaking for parts but that did not feel right. So now the new owner can bring the radio back to life. I have purchased a non valve radio with auto ATU.

I would like to thank those who have offered assistance – thanks J

To clarify, I see the meter mechanically pegged(full right, hitting the end of its travel) while attempting to peak the drive control in either TUN or CW mode. This occurs with the CAR control reduced all the way(FULLY Counterclockwise). The peak where the reading is beyond the range of the meter is approx 20 degrees of rotation of the Drive control, so the only way I am able to peak the drive is to estimate the center of the region where the meter is full right. This is occurring on all bands including 10m.

Is the meter switch set for Ip or ALC? If it's in the RF position there is a pot to set the relative RF signal level calibration.

My radio is Ham Radio...CW is Real Radio

You can always peak the Drive control using receiver back ground noise or the 25khz marker signal, but that is a work around and you should not have to do that.

Are you saying with the meter in ALC position and the CAR pot full CCW when you flip to Send the meter deflects to the far right and hits against the peg? Do you have any RF drive? Can you see any RF power deflection on your wattmeter if you have one in line or on the RF relative power position of your panel meter? If no RF drive you probably dont have the ALC bus powered. With zero vdc on it the meter will deflect hard to the right.

If you have a DMM or VTVM locate the AGL wire wrap terminal post on the IF board (use Xray view of the board from the service manual). Flip to Send and see if you have any dc voltage on AGL. If not then you may have a bad Aux relay contact. On rare occasions the RF-1 voltage supplied to the RF board is missing. I have had couple of TS520s that had bad solder connections at the RF-1 terminal post on the RF board. The ALC bus is powered via RF-1 being applied to the RF board. From there it is switched to AGL terminal by Aux relay contact RL1-1.

Mike:

If this comment is directed to me? Then I offer:

If he is peaking on receiver back ground noise or marker signal the meter is always in ALC position in RX mode. I was just trying to tell him that on a well aligned Hybrid the ALC peak in Tune mode should occur very close to same position in RX mode. So he could peak the Drive in RX mode and leave Drive control alone and proceed with loading. He was describing the only way he could peak the drive and that wasnt a true statement.

Far too many 520 owners use this work around on 10 meters because they believe it is normal to have no ALC indication and that is a myth. Never had one leave the bench that didnt have ALC indication on 10 meters after good alignment. Never as strong as lower bands for all the reasons I previously explained in the LC ratio discussion.

I will be very interested to hear if he has any RF drive at all. It sounds like he has no ALC bus voltage. If that is true then would have instant pegging of the ALC indication when flip to Send and no TIF and of course no RF voltage at Finals control grids to peak with Drive control. Could be wrong, but usually an easy fix.

I only stuck my nose in due to seeing all the discussion about screen grid voltage. Screen grid voltage was essential for ALC indication strange that you can have good ALC indication with the SG switch off and -100vdc applied to the Finals screen grids!

Back to the soldering iron. Just needed a little break.

50003. Greetings! And TS-520 repair question

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-08 03:06:07 UTC
From: Mike Allard
Topic: 50003 Message: 50003

I just picked up a TS-520 as my first HF radio, and it's overall in excellent shape - except for what seems to be a cold solder joint under VC1 on the RF board (the frontmost variable capacitor driven by the Drive shaft, in the very front of the radio). This shows itself as intermittent operation of the drive knob particularly on 80 meters; pushing/wiggling the knob vertically, or tapping on this particular capacitor with a plastic instrument, causes the connection to make and break (increase/decrease in signal / meter deflection).

(Apart from this issue, the radio performs very well, receiving quite clearly and putting out over 100 watts on all bands.)

My first question: Does it sound like a cold solder joint to you?

My second question: How do I get to the bottom side of the RF board to fix this? The service manual describes removing the coil packs to remove the RF board, but doesn't go into much more detail than that. I want to make sure I can get this thing apart and get it back together in working order.

(As an aside, it looks like the drive shaft sprocket and the capacitor sprocket are misaligned vertically by about 3-4 mm for this capacitor - perhaps this chain has just been too tight and that has caused this issue by pulling up on the front edge of the capacitor? I plan to move the drive sprocket back into place so that it's vertically aligned like the other two chains are.)

Thanks in advance for any help - and hope to catch some of you on the air soon!

- Mike, K9MJA

Mike:

First of all close (fully mesh) the plates so you can grasp the capacitor without risk of damaging the plate spacing. Then grasp the capacitor body and rock it as you observe the Marker signal or off air signals on the S meter. This hasnt got much to do with chain tension. Just poor soldering.

Unfortunately no good way to access the RF board solder pads. The Het Osc "hanging board" blocks full access to most of the air variable 5 solder pads.

Best chance at effective repair will require pulling the bandswitch shaft and remove the Het Osc board and the 1st shield. This means undoing the leads on the 4 or 5 wire wrap terminal post on the RF board (depending on board rev). When going back cant rewrap the old unwrapped lead wires. Need to tack solder replacement jumpers. Need good clean pins to do this.

While Het board is out do a very good visual on the slug tuned cores for frozen and cracked cores. Now is time to replace them (very common problem with all 520 rigs).
Then best approach is to remove the old solder at the these heavy square tabs and clean the post and re-solder them. Sometimes you can get lucky by just reheating the existing solder, but going to trouble to access I would remove as much of old solder as can.

Other option would be to contact Bob Mansker KE5FTF who has a lot of TS520 parts and see if he has an RF board with the hanging boards. If so, again inspect all the ferrite slug tuned cores while you have good access to remove any frozen or cracked ones.

Lastly, I dont know if you could apply any Silver Conductive Ink with an artist brush with the Het Board and Shield in place. Might be worth an attempt especially if you have only one bad post or one that has relatively decent access. The worse one is almost directly under the Het Board.

Not a fun repair.

From: wo7t@...
Topic: 50006 Message: 50006

In 1981, I purchased MY first new rig TS-520SE. A sage OT Elmer advised I should buy spare relays for the rig at that time. In 1982, Kenwood of Compton.CA shipped me the following parts:

S51-4016-15 TS-520S RELAY / RL1
S51-4017-15 TS-520S/820S RELAY /RL2

They have sat in un-opened plastic bags, as packed by Kenwood since then

in a shipping box, lost at the back of the ham shack cabinets. Not so sage

advice I would say given the durability and longevity of the hybrid kenwoods
and probably being suitable for decades of relay cleaning before replacements.

Nonetheless, brand new original relays of > 30 yrs for sale - $40 for the pair plus $5.95 shipping priority USPS. They're going up on swap boards soon, and just wanted to start here first with crowd restoring and fixing these.

Terry -

Thanks for the thorough description of what I need to do. I had been poking around your site last night before you replied, so your name and call were familiar to me when I got the reply.

I like the way you added the "not a fun repair" epilogue to the end of your missive. :)

I've seen other articles on here about reconnecting the wire-wrapped leads - which is good. I would have probably tried 2 or 3 things that didn't work before simply cleaning the post and jumpering the lead to it.

I do have some solder experience, but not a lot - and I do have some electronics experience, but not a lot. My most recent electronics exercise was adding an EQ bypass switch to my Ibanez electric bass. Not quite the same world as this repair!

Nevertheless, I'm a-gonna attempt this sometime in the next few days. I expected to have to do some minor repairs on this radio over time; this is likely just the first. Thanks for your detailed instructions. I'll make sure to take a good look at the coil slugs while I'm in there. Apart from broken or frozen, is there anything in particular I should look for?

Thanks and 73!

- Mike, K9MJA

Marq,
You are going to have to be more specific about what "bad readings" means.
There are many places that can/will cause problems. The DG-1 unit immediately comes to mind. One of circuit boards has about 18 "thru-holes" that over time will may cause the display to not function correctly. The PD/VCO unit is another...and the main VFO is another..and so on.
Look on Pg's 40, 41 of the TS-820(S) Service Manual to start with

Mike

I believe you said rig was new to you. Have you tried it on 10 meters to make sure it has not been CB hacked? If not, do that before removing the Het Osc board to repair the bad VC-1 solder connections as you can more easily replace the involved Het Osc crystals while you have the Het board out.

If you encounter cracked or frozen coil cores come back and ask about favorite methods for freeing and removing them. Several of the members can help you with what they have found works well.

Good luck
Terry K9TW

Subject: [TS-520_820_530_830] NOS RL1 /RL2 for 520 820 Rigs

In 1981, I purchased MY first new rig TS-520SE. A sage OT Elmer advised I should buy spare relays for the rig at that time. In 1982, Kenwood of Compton.CA shipped me the following parts:
S51-4016-15 TS-520S RELAY / RL1S51-4017-15 TS-520S/820S RELAY /RL2
They have sat in un-opened plastic bags, as packed by Kenwood since then
in a shipping box, lost at the back of the ham shack cabinets. Not so sage
advice I would say given the durability and longevity of the hybrid kenwoodsand probably being suitable for decades of relay cleaning before replacements.

Nonetheless, brand new original relays of > 30 yrs for sale - $40 for the pair plus $5.95 shipping priority USPS. They're going up on swap boards soon, and just wanted to start here first with crowd restoring and fixing these.

Terry -

I just took the bottom off of the radio for the first time. In doing this, I noticed that two screws were missing from the bottom and a third screw was a little loose. Maybe time to order a hardware kit (or hit up the local hardware store for a couple matching screws).

I posted a new photo album https://groups.yahoo.com/neo/groups/TS-520_820_530_830/photos/albums/57074860 here with two pictures in it.

I meshed the plates as you suggested and started wiggling the capacitors - with the radio unplugged. VC2 and VC3 appear solid; VC1 had a quiet but distinct "click" as I moved it, and I could see one of the pins move up and down slightly from the top side of the board, as noted in the "Loose VC1" picture I posted.

In looking at this from the bottom, it looks like my first task might be to try to fix the known loose connection. I've marked it on the "Bad Solder Joint" picture I posted. I might be able to do this by just removing the shield and not removing either of the neighboring boards. What are your thoughts?

You know, I'm not sure if we tried it on 10 meters; I know we did 20, 40, and 80. The solder at the corners of the Het Osc board looks a little different than the solder on the other boards (maybe it's been out before?), but the 4 wire-wrapped terminals coming up through the RF board look to be exactly the same condition as the other wire-wrapped terminals for the other hanging boards (so maybe it hasn't been out before). It sounds like I might need to make another "quick" trip to my friend's house (he lives 40 minutes away) to test this out - I don't have an antenna or another radio at home to compare to. If his radio and mine can receive the same signals at the same frequencies on 10, then I should be good.

- Mike, K9MJA

P.S. The seller offered a 14-day return policy on the radio; I received it 7 days ago. A bad solder joint is one thing; if it's been modified for CB, then I'm not yet sure how I'll proceed. I at least have to test it out on 10 and hopefully find out it's not on 11 or 12 or whatever CB is. :)

Just a short comment. I could be wrong but if your TS-520 has the "HET" socket on the rear panel and you have access to a frequency counter, connect the frequency counter to the TS-520 rear panel's "HET" socket. The HET crystal oscillator frequency will be displayed on the frequency counter. Set the Band Switch to each 10 meter position and note the frequency displayed on the frequency counter then compare the frequencies with the 520's RF Unit schematic HET crystal frequencies.

Terry -

Of the three highest-frequency crystals on the Het Osc board, the two highest frequency crystals say 37.995 and 37.395 (matching the schematic). The third one starts with 36 (which could match the 36.985), but I don't have a small enough mirror to get in there to read the rest of the frequency.

So, maybe I'm good on 10. :)

It appears you have factory Het xtals installed in the 10 meter bandswitch positions.

If you can access the square post where you see the movement then go ahead and try to reheat it and apply some additional solder and try to get it to wet to the square post from the variable capacitor. You may get lucky and that connection may be the only source of your intermittent receive. Would do that before pulling the Het Osc board.

Next thing you need to purchase or make is a dummy load. A must have accessory for transmitter loading and testing.

No reason to drive 40 miles to friends house to test your radio.

The intermittent receive may have been the only operational issue that caused the seller to unload this radio. Would be nice if had mentioned the problem, but we truly live in a Caveat Emptor world even in what use to be the Ham Radio "Fraternity"!

You might want to go back and negotiate for a partial refund?

Terry -

I have already purchased a MFJ-949E tuner with an internal dummy load; I tested it as well at my friend's house. I think its meters need to be adjusted a bit, but that's not a big deal.

I bought the radio on eBay (caveat emptor indeed), and overall I'm really quite pleased. I expected to have to make some minor repairs and adjustments along the way, so I'm not even really bothered by this. It's all a learning experience to me.

I'm even chronicling my adventures with this radio http://k9mja.blogspot.com by blogging as I go - it's giving me the opportunity to write as well as learn.

Thanks for all your help so far - I'll definitely keep the group posted on my progress.

Topic: 50003 Message: 50019

If building a dummy load is not your cup of tea then you might consider purchasing a new dry 50 ohm dummy load from MFJ.

The MFJ-260C has a maximum constant RF carrier power rating of 300 watts for 30 seconds, 100 watts constant RF carrier power ratting of 1.5 minutes, and 50 watts constant RF carrier power rating of 3 minutes. Cool down periods of 2 minutes apply, see the MFJ-260C manual for details.

I use the MFJ-260C 50 ohm dry dummy load on my bench when testing transmitters such various transmitters/transceivers such as the DX-40, HW-101, SB-100 and SB-400 transmitters/transceivers and my modified to 10 meter AM, Johnson Messenger One, II, and 223 11 meter transceivers. Never had a problem. Price is $39.95 plus shipping from MFJ. The MFJ-260C does not come with a short coax jumper between transmitter/transceiver and dummy load. You can make one easily out of a short piece of RG-8x coax and 2 PL-259s and 2 RG-8x UG-176 reducer or you can buy the coax jumper at various sources.

There's a brand new MFJ-260C on eBay, same price $39.95 plus $11 shipping under eBay ad #381022593130, no coax jumper included.

You can also use the wet dummy loads, Heathkit Cantenna (most are used and prices vary with or without oil) or a new MFJ 250 comes with 1 gal of oil for $69.95.

Not only will a 50 ohm dummy load be used during transmitter maintenance testing but it should always be used when tuning the transmitter, regardless what type of antenna and/or with or without a tuner in use, before switching to the antenna.

Mike,

You will need to ensure you do not exceed the MFJ-949E dummy load's
steady maximum RF carrier limits which are:

300 watt steady RF carrier, max 30 seconds with a 3 minute cool down time.
100 watt steady RF carrier, max 90 seconds with a 1 to 2 minute cool
down time.

The above limits are on page 2 of the MFJ-949E manual. The above limits
are the exact same specifications the MFJ-260C 300 watt dummy load has.

50023. Hybrid Net Update (November 9 , 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-09 23:50:08 UTC
From: Mark Gilger
Topic: 50023 Message: 50023

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There were 29 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)

2 running TS-530(x)

5 running TS-820(x)

7 running TS-830S

0 running TS-511

0 running 599 twins

I was running my Drake 'C' liine & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were 19 stations checking in under fair band conditions. He had the following number of radios checking in.

3 running TS-520(x)

1 running TS-530(x)

4 running TS-820(x)

4 running TS-830S

0 running TS-511

0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S & Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday□s net total 45, Sunday□s total = 38 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

Nathan

Are you saying that if you turn the CAR LEVEL POT down from its 1000 position the ALC indication will still peg full scale? Even if you turn it full CCW?

When I watch this I am screaming turn the Car Level pot down man! That is what you would normally do any time ALC indication pegs full scale. Just simply reduce the CAR level.

If rig is working correctly when you reduce the Car level you lower the bias voltage that it is applying to the Balanced Modulator diodes lowering their conduction and lowering the double side band suppressed carrier output from the BM. The Car pot normally provides from 0.0 vdc to approx 0.60 vdc at full CW position. These are germanium diodes and with 0.60 vdc applied they would be turned on hard.

Go to the BM wire wrap terminal on the Generator board and connect your VTVM or DMM and measure the bias voltage thru the complete range of the CAR LEVEL Pot.

If you have an open BM diode you will read 9vdc and not 0.0 to 0.6vdc.

Terry K9TW

Yes, ALC will still peg the meter when CAR is fully CCW. Measuring the BM terminal I read 0.578v in recieve, and 0.324v in send. The odd thing is that this did not change at all through the adjustment of the CAR control.

Topic: 49981 Message: 50026

OK then you have found the reason for instant max DSBSC output from the BM. Now need to find out why.

If you are telling me that you have 0.324vdc at BM terminal with rig flipped to Send at any position of the Car Level pot including full CCW then the germanium BM diodes are fully forward biased (turned on).

Question is why?

1. Is the Car Pot knob actually turning the Car Pot shaft? Never seen a broken pot but possible. Usually people tighten the knob lock screw too tight and it pinches the shaft which is a hollow tube for concentric Mic gain pot shaft and when they do that the Mic gain knob moves with the Car pot knob. Just need to snug the screw. You can remove the Mic gain pot knob to look at the Car level shaft (hollow tube) to see if it is turning as you move the Car knob.

Maybe someone installed the knob wrong and has offset the zero? Very easy to check. Loosen the lock screw and remove the knob and then set the hollow shaft full CCW and then install knob and align white mark at Zero and snug the screw. If in current state you can turn the Car knob from Zero to 10 and find the stops then not likely mis adjusted.

2. Place your DMM on the CV wire wrap post which is the wiper of the Car Level pot. You should see from 0.0 to approx 9.0vdc as you run the pot thru its full range.

The reason you see 0.0 to 0.6vdc at BM instead of 0.0 to 9.0vdc is there is a series dropping resistor 18k R35 that comes in to play when diodes are turned on and forward current causes an IR drop.

Report back your CV findings.

Sorry I missed commenting about 0.578 vdc in RX mode.

With Car pot at Zero you should have 0.0 vdc at BM in Rx mode.

With Car pot at 10 you should have approx 0.50 vdc to 0.60 vdc in Rx mode.

Makes me think that pot knob has been offset or the set screw is loose. Again make sure the range of the Car Level pot is from Zero to 10 with positive stops.

50028. How long to "tune" TS-820S?

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-10 15:31:29 UTC
From: David Boothe
Topic: 50028 Message: 50028

Hey, folks. Having a lot of fun with my TS-820s. I use multi-band antennas (G5RV jr and trap dipoles) and an LDG AT-600 ProII to tune them with the 820s. Got a new antenna and the AT-600 ProII tuner sometimes takes a while

to tune up and establish a memory setting. Very quick thereafter. The question is: should I worry if it takes a while for the AT-600 to establish a match? Sometimes it takes 20-30 seconds with the 820s providing output in

"tune" mode. Is there a "maximum time" I should observe?

Thanks!

Dave

Dave,
with the rig in "tune" mode and already tuned up for proper resonance on selected band, 20-30 seconds should not create a problem.
The problems start when you operate the rig in an out of resonance state.

I just posted a pic of the front subpanel of a TS830S that shows what screws not to remove when you (ignorantly and over zealously ;-)) try to remove this panel. It is a pain in the... I bought a non-working smashed parts unit & unfortunately, I got it to work. Which meant I had to fix it's appearance. I hate cannibalize radios. Seems sacrilegious, especially Kenwood Hybrids. Anyway, Kenwood did not stamp "do not remove" near these screws, which turn out to be ground screws with hidden wires soldered to them on the other side of the panel. They are identified on the exploded view in the SM but I did not find any warning.

Hopefully this will prevent the rework I had to do. My plan is to straighten out the panel & try to reassemble and then still have it work, but look presentable. - 73 Bob

In addition to shortening the life of the Final tubes by consistently leaving it key down for "long" periods of time in off resonance state you also subject the 12BY7A driver tube to stress. Not from off resonance, but simply key down time as it is running Class A and just about at the max of the plate current and screen grid current ratings.

Definition of "long" time will always be subjective. I have lost one Driver tube during testing of the RF drive voltage at the control grids of the Finals. During that testing I was measuring the RF drive on all the bands one at a time and I failed to let the Driver tube rest as I switched bands.

In your TS820 owners instruction manual under Transmitter Tuning Caution Note it says that if the plate current is much above 60ma to not leave the rig in Send for more than a "few seconds". Now the truth is if you do this it typically wont result in an "acute" failure, but it can lead to a "chronic" failure.

Note 2 in this same section says not to leave rig keyed "over a few minutes" or the Driver tube may be damaged. Not sure who wrote this, but I would never leave rig keyed for one minute let alone a "few minutes" even with the SG switch turned off. A real good way to lose the Driver tube. In 30 seconds the Driver tube shield will be too hot for you to touch. Tune mode does not change the Driver tube plate dissipation.

I cant imagine why it would take 30 seconds for an auto tuner to correct the reactance and present a match of course I have never owned one.

Dave and Joe,
Thanks for the prompt and helpful replies. Joe, I’m thinking the resonance thing takes care of itself.
When I leave the AT-600 in auto-tune mode and switch bands/antennas, the tuner doesn’t start until It gets RF from the radio, which doesn’t really happen until you dip the plate when tuning for the new band. Then the tuner kicks in. The tuner doesn’t usually activate when you are just tuning the drive for max deflection. If the tuner does start before I can dip the plate, I just immediately stop the tuning and put the tuner in manual until I dip the plate and get resonance and RF output.

Dave,

Your comments suggest that you tune your 820 transmitter into the tuner that's most likely not tuned to resonance. You should be tuning your 820 transmitter into a 50 ohm dummy load FIRST. Once the 820 transmitter is tuned properly, then switch the 820's output to the tuner's input and allow the tuner to adjust itself without you touching the 820's DRIVE, PLATE, and LOAD controls.

Thanks, Terry. Helpful as always! I watch the plate current during the process and it is indeed pretty low. My main worry, just as you say, is the 12BY7A driver. I caught both references in the manual—you pay your money and take your chances, I guess.
Tuners are a reality in my world of multi-band attic antennas (G5RV jrs and trap dipoles—antenna restrictions), but it seldom takes more than a few seconds for a match. If the tuner struggles for more than a few seconds, it’s usually on a first match (no memory yet) or (worse) no match forthcoming.

Mike,
I hear you—that is no doubt the best way to proceed. However, the Pro II doesn’t have a dummy load and connecting one would mean added switching, coax, space requirements, and general complexity. I have two dummy loads (the ‘Cantenna’ stays in the basement unless I’m doing amp work—too oily!). My MFJ manual tuner has a 100W load and could be switched in and out for the 820S (with above considerations), but the Pro II is very quick (< one second) once it’s got the settings in memory. Anyway, you’ve given me something to ponder and I will!

Mark,
Congratulations on the ticket!
You will love the TS-520.
Personally I think you are a head of the game starting out with this rig and being new to amature radio.
It is fun to use and tune up, and you will learn more using it rather then a "plug and play" newer rig. I would encourage you, (as you said you already are), to read the manual and the service manual and really learn about this radio.
If you have not found it yet the one thing that helped me when I first started using mine, coming from a Yaesu 450d, was the following two explanations on how to tune up the radio.
The manual can be a little vague;
http://www.k4eaa.com/tune-up.htm http://www.k4eaa.com/tune-up.htm
http://www.hybridrestore.com/tuning-your-hybrid/
http://www.hybridrestore.com/tuning-your-hybrid/
Both these guys are on this list and not only a great source of information, but you can get many parts you may want or need for your radio from either of their websites, and they are great to do buisness with.
The thing I like best about the hybrids is you can work on it yourself. No surface mounted microscopic parts in there!
I just striped and pained the case of mine, and while I was at it pulled the VFO and cleaned and lubed everything, and cleaned all the switches.
This group has very knowledgeable people on it, (More so than me) who are very willing to help expalin anything you are not sure about.

Short reminder to self:
After cleaning and re-flowing board pins on DG-1 for intermittent random display problems, display continued to have lack of MHz digits with remaining KHz digits "locked," regardless of frequency or band change. Take apart. Add solder to via's, and topside IC pins on board etc...still had problem...

Re-reading through Group archives, saw info about inputs and controls for the DG-1 cct...Read two letters: "DH" digital hold....oh ya...totally forgot about that dam'd button! (especially forgot it normally does NOT display MHz digit- a big clue)

You'd think I'd be too embarrassed to admit this oversight..but now I will find this post when it happens to me again a second time!

I did a similar thing in testing out my new-to-me TS-520... I spent 20 minutes trying to figure out why I couldn't tune in the SSB conversations that I could clearly hear on the other radio.

Until I realized I had forgotten that I had pushed the WWV button.

Nathan,

The TS-530 service manual has an excellent write up on how and why the TS-530 shifts. The discussion starts on page 3 in the service manual titled "Circuit Description". If you do not have the TS-530S service manual, you can download it from my website

www.w5rkl.com

Click on the Manuals, Docs, and Mods link at the top of the page. When the page comes up, scroll down to the TS-530S/SP listing and click on link #2.

None of my radios (Kwd or Yaesu) show any change in display from RX to TX modes, unless the RIT is turned off zero.
I hear so many answers to my CQ so far off freq that I could miss them with the narrow filters on ! I Would Bet they are fiddling with RIT or XIT offsert to match the shifting display numbers between RX and TX modes !!!!
PLEASE READ THE MANUALS !!

You must not own any KW hybrids with digital displays or have very little experience with them. By design the Transmit frequency shifts up 800 hz up and the digital readout displays that. Has absolutely nothing to do with the RIT. KW did this so the actual operating frequency is displayed.

On the TS530 and TS830s the VFO frequency shifts up 800 hz in CW mode. All you have to do is place the Mode switch in Tune and you will see the last digit go up 800. To make the math easy on yourself set VFO to 7.000 or 14.000 and place rig in Tune and you will then see 7.000.8 or 14.000.8. Assuming L4 in the VFO has been adjusted properly during alignment.

If you place the mode switch in CW mode you then have to flip to Send to see the digital display read up 800hz.

The TS820 works a little different (uses 3 Carrier Osc crystals same as the 520) and you have to flip to Send in both Tune and CW to see the digital display read up and most hit my bench with a 700hz up shift or .7 on the digital display.

I have the original TS520/no S . I guess that's why it has 3 index marks over the round analog dial, one for USB, another for LSB and the center mark for CW. Now it makes sense. The TS440s was my first digital display and it took me a long time to get used to it but it doesn't shift Display numbers like the newer (old) Hybrids. When you tune in WWV it is right on 5.0000, 10.0000 or 15.000 ETC.... USB, LSB or AM mode.
Transmitting a CW Carrier is right on the freq. the display says !
Synthesyzer circuits give me a headache going way back to the days of the GE Phoenix and Motorola Syntor and Maxtracs.

Yes the TS520 and 520S have three Carrier Oscillators. No such scribe marks required on the 820, 530, or 830 analog dials.

Yes with the digital display KW hybrid models if you tune to 10mhz or 15 mhz and listen to WWV the digital displays will display 10.0000 (530/830) and 15.0000 (820) in LSB, USB and CW modes. On the 530/830 if you place mode switch in Tune while listening to WWV you will see the digital display read 10.000.8. No reason to have mode switch in Tune in Rx mode.

As I mentioned and as Mike W5RKL directed the Service manual circuit descriptions explain why the transmit frequency is shifted up 800 hz and displayed properly as such.

Sometimes people have very low ALC indication when loading the radio requiring full open on the Car Level pot. I always ask if they have the CW filter installed. If so I first have them try peaking the ALC indication by adjusting the CW-T Carrier Oscillator trimmer cap (TC-1). Can usually improve the ALC indication when you get the Carrier Osc set to 8830.7 mhz which should be the center of the optional CW filter passband. However, this year I have had to replace at least 4 of the YG-88C 500hz CW filters as the Fc has shifted significantly. Beginning to get a bit nervous about being able to continue to find used pulls. Of course a crap shoot if they are any good.

John and others,

Quite a few transmitters and transceivers shift the VFO output frequency, depending on the MODE switch setting. For example, the Heathkit HW-100 and HW-101 VFO, I just happen to do a lot of Heathkit repairs and have the HW-101 and SB-100, SB-400 and SB-401 on hand. Heath calls their VFO's, LMOs (Linear Master Oscillator), and they all have a terminal on the rear labeled "BIAS". What the heck does the BIAS terminal do on a LMO (VFO)? If you had an HW-101, a frequency counter, and a DC volt meter, you would find out what it does.

The LMO bias terminal is fed a "positive" or "negative" DC voltage depending on the MODE switch position. The BIAS voltage is used to forward/reverse bias a diode inside the LMO and that diode, when biased properly, acts as a switch to add or remove a variable 3-30pf capacitor "shift" capacitor.

HW-101 LMO output based on the LMO BIAS voltage

LSB bias voltage is +50VDC TX/RX
USB/CW bias voltage is -70.8VDC RX and -62.8VDC TX

LMO (VFO) output frequency on ALL bands with dial set to 0. The LMO (VFO) output frequency will change when tuning up or down the bands BUT the LMO (VFO) frequency range does NOT change regardless of the band switch position! This is important to understand since the KW hybrid VFO frequency range does NOT change as some hams have been "misled" to believe.

LSB RX/TX = 5502.9Khz with +50VDC applied to the LMO's BIAS terminal
USB/CW RX/TX = 5500Khz with -70.8VDC applied to the LMO's BIAS terminal.
BIAS voltage is -8.6VDC less with MODE switch set to TUNE. The 8.6VDC difference in TUNE mode has no affect on the LMO's output frequency.

Members can do similar test on your 520. The VFO output signal is present on the rear panel's REMOTE VFO socket, pin 1 with ground on pin 2. Leave the 520's FUNCTION switch set to VFO (12 o'clock) position. A frequency counter connected to those pins will display the VFO output frequency without disconnecting the VFO output cable at the rear of the internal VFO. If you have the 9 pin jumper plug simply pull the plug and jumper pins 8 and 9 with a short piece of wire so the internal VFO has power then connect a frequency counter to the remote VFO socket's pin 1 with ground on pin 2. The counter should display the VFO output frequency (range is between 5.500Mhz at the low end of ALL bands to 5.000Mhz at the top of ALL bands).

Mike,

Great information. I was thinking of getting one of these digital readouts for my TS-520;
http://www.electronicspecialtyproducts.com/dd103.html
http://www.electronicspecialtyproducts.com/dd103.html

It plugs into the remote VFO socket in the back.
So, it sounds like your description of using a frequency counter to get the VFO readout from that output is exactly how this device works, and if so it sounds extremely easy to just use a cheap frequency counter and put it in a home-brew box and hook it up myself the way you describe, and I will have essentially the same exact thing a lot cheaper. And segwaying that into Terry's discussion of the three carrier oscillator crystals in the 520 for CW, LSB, or USB that displayed frequency output would be my actual operating frequency depending on what mode I select. Correct?

Thank you and 73, Tom Bewick, K2BEW

Sorry one other question on the output of the VFO and the discussion of the off set.

This simple counter from Hendricks QRP kits looks like it would work well and it has the ability to read the VFO of a radio and it has an adjustable off set to display the actual operating frequency.
http://www.qrpkits.com/freqcounter.html http://www.qrpkits.com/freqcounter.html

Would this be what I would want for this application to be able to read my operating frequency off the the external VFO output on the TS-520?

Thank you,
Tom Bewick, K2BEW

Well this is embarrassing... Found some kind of mod hidden in the front panel wire harness. Not really sure who, how, or why, but it was a voltage divider supplying a fixed CAR signal. This is a formerly-rednecked radio, but had stock crystals, so I hadn't expected to find this level of inexplicable modification. The pot tests fine, so it wasn't bypassing a bad pot.

In the process of reversing this... Stay tuned...

Tom,

I do not have any experience with the DD103 digital display. Therefore I will not make a comment on it's use. I think hams today rely entirely too much on digital displays.

The KW hybrids also have analog dials. The analog dial number is added to the band switch setting to determine what the frequency is. The analog dial covers the entire 500Khz of each band the transceiver is designed to operate on. For example, if the TS-520 band switch is set to 3.5 and the analog dial is set to 100, what frequency is the 520 tuned to? It's easy, the "100" is the Khz segment of the dial while the 3.5 is the Mhz segment of the dial. You add .100 to 3.5 and you get 3.6. The analog dial starts at 0 which is the bottom end of ALL bands. If the band switch is set to 3.5 and the VFO analog dial is 0, what is the frequency the 520 is tuned to? Again, it's easy, add 7.0 to 0 and you get "7.0". Move the analog dial to the first small tick mark, that's "25" then add .025 to 7.0 and you get 7.025. it's easy, one just has to learn how to use it.

I think you misunderstood what I was trying to say. You cannot use a simple frequency counter such as a Sinometer VC-2000 or Heathkit IM-4100 as a digital display by connecting either counter to the TS-520's remote VFO socket pins 1 and 2. If you were to connect a Sinometer VC-2000 or a Heathkit IM-4100 frequency counter to the remote VFO output socket, pin 1 and 2, on your TS-520, all you would see on the frequency counter would be the VFO output frequency which would be a frequency between 5.500Mhz and 5.000Mhz, depending on where you tuned the VFO dial to. The VFO in the KW TS-520 has a tuning range between 5.500Mhz and 5.000Mhz and that tuning range does NOT change to another tunng range when the band switch is changed.

I recommend you spend some time studying how the 520 stages work together to process both receive and transmit signals. The VFO is only one of many oscillators in the 520 and it is used in both transmit and receive.

50053. Re: [TS-520_820_530_830] veterans day

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-12 03:39:05 UTC
From: Tom k2bew
Topic: 50040 Message: 50053

Thank you Joe,
I posted this on my blog today;

My son Joshua is a boyscout in Troop 114 in Valatie, NY, and they host a 5K run in our village of Valatie, NY every Veteran's Day that is followed by a ceremony in the town park to honour veterans and is hosted by the VFW.
It was my honour to be asked as a veteran to stand with the brave men and women from our village that are veterans going back to WW2. I was humbled and felt inadequate. I was an Army nurse in the reserves and I was mobilized to active duty during the war in Afghanistan for a year and sent to Ft. Sill Oklahoma where I worked in the ICU and cared for soldiers and their families, many of whom were just back from the theatre of war. I had joined the Army with the intention of going to Iraq or Afghanistan to take care of soldiers in theatre, but found myself in Oklahoma instead. I felt like I did not do enough, and not what I signed up for, but in retrospect I feel I did that which I had signed up to do, and I took care of soldiers, it does not matter where I was.

My wife and I recently went on a trip to Hawaii for our 25th anniversary in October 2014 and we had the opportunity to visit Pearl Harbor and go to the Arizona Memorial. As I stood today in the village park with those Veterans I was pondering how I felt standing at the Arizona as I looked down into the water at that rusting wreckage of that great ship. I thought of those who lost their lives in service of our country that were on board. As I stood there I could smell the oil that was bubbling out of the wreckage to the surface of the water. The park ranger there said a quart of oil a day leaks from the ship and is considered by Veterans of the war to represent the tears of those who died.
I took this picture from that spot, you can see the oil slick;
https://2.bp.blogspot.com/-orWRRJrhDGQ/VGK9KerzCfI/AAAAAAAAgLc/OwdDWa3WGWk/s1600/100_2081.JPG
(The above oil slick picture is copied into the email, but probably will be striped off in yahoo, you can see it here if it does not make it;
http://k2bew.blogspot.com/2014/11/veterans-day-2014.html
http://k2bew.blogspot.com/2014/11/veterans-day-2014.html)

So, This Veterans Day, whether or not you served, or not, and whether or not you went to war, or not ,we can all honour and remember those who have served and made the ultimate sacrifice, and continue to serve ourselves in whatever capacity we are able, and wherever we find ourselves.
Blessings and 73,
Tom K2BEW

Subject: [TS-520_820_530_830] NOS RL1 /RL2 for 520 820 Rigs

In 1981, I purchased MY first new rig TS-520SE. A sage OT Elmer advised I should buy spare relays for the rig at that time. In 1982, Kenwood of Compton.CA shipped me the following parts:

S51-4016-15 TS-520S RELAY / RL1

S51-4017-15 TS-520S/820S RELAY /RL2

They have sat in un-opened plastic bags, as packed by Kenwood since then

in a shipping box, lost at the back of the ham shack cabinets. Not so sage

advice I would say given the durability and longevity of the hybrid kenwoods

and probably being suitable for decades of relay cleaning before replacements.

Nonetheless, brand new original relays of > 30 yrs for sale - $40 for the pair plus $5.95 shipping priority USPS. They're going up on swap boards soon, and just wanted to start here first with crowd restoring and fixing these.

Gentlemen,

I noticed some days ago that digital read out of my TS-820S is indicating wrong frequency on 21 and 28 MHz bands. It is 4 kHz below on 21 MHz and about 10 kHz below on 28 MHz. However, VFO-dial and xtal-calibration signal are indicating the correct frequency (btw, matches to reverse beacon results too). Does this ring the bells to anyone? What would you suggest?

The DD-103 is only as good as when you calibrated to your radio. It doesn't come calibrated it take you about 10 minutes to do it. I know as I own one, see my pics in the photo section Neil

Mike,
Thanks for the explanation, I think I understand now what you mean now about the 5.000 mHz -5.500 mHz. tuning range. Similar to an AA5 AM tube radio with an IF of 455, it does not change from the 5.000mHz except it has a 500kHz range it travels through that coincides with the tuning range of the VFO.
I was debating if it would be a good idea of getting one of those digital readouts anyway because I am thinking of getting the external VFO so I can work split, and if I have a frequency counter plugged in to the output all the time I will not be able to do that.
I am going back through the service and regular manual and studying how the stages and oscillators all work too. This has been a good discussion.
I do understand the basics of how the analogue frequency is displayed, I have used it a while now, I just thought it would be nice to have a digital read out, and the Kenwood DG-5 and matching installation kit seems to be hard to find and usually go for a lot more then they are worth.

HI All,
I was given a TS-530S that's been in a closet for some time needing repair. The receiver is mostly deaf. I can hear the calibrator signals but they are barely audible. How loud should they be?

I haven't checked TX yet but was told there is no power out.

Any suggestions would be welcome, I'm not used to dealing with these really big parts haha.

Dave,

You did not say whether you have the TS-530 service and operator's manual or not. If you do not have both manuals then I recommend you download them and spend time studying them first before you attempt to service and operate your newly acquired TS-530. You can download both manuals from my website

www.w5rkl.com

Also, you did not specify what test equipment, if any, you have and what electronic troubleshooting knowledge and skills you have in servicing complex electronic equipment such as the TS-530.

Kari,
It seems the digital display is a bit the Achilles heel of the TS-820s. I had an issue with mine with wrong readings as well, but mine were a fixed offset on all bands, not just 21 and 28 mHz. The display would track the VFO changes, but the offset was always there and was different on each band. It turns out that mine was the result of a bad divider chip in the DG-1 unit that controls the display.

I'm told though that a bad chip or other part is usually not the cause of the display issues with the 820S. It's usually a need to clean the Molex contacts to the DG-1 unit in the radio (there's one on the top and bottom of this unit, located by the VFO in the radio) or has to do with deteriorating or just bad solder joints on the boards, especially the "through hole" connectors. Just google "TS-820S display problem" and you'll see quite a bit of guidance on this issue (I've read them all).

Also, there are experts on this Board who know a lot more than I do about it and may want to comment as well. You are not alone—these display problems are apparently pretty common with the 820S.

Tom,

I uploaded a video to my website explaining how a simple "single conversion" AM receiver processes and converts a 550Khz signal from the antenna to the speaker. Simply go to my website

www.w5rkl.com

then click on the Video page link at the top of the page. When the Video page comes up, scroll down to the "Simple AM receiver signal processing" and click on link #1. The video explains in simple terms how the receive signal, 550Khz in this case, is processed from the antenna to the speaker.

After you watch the video, try to determine what the Local Tunable Oscillator tunable frequency range would be in order to tune from 540Khz to 1700Khz (the expanded broadcast band).

Also, if the tunable oscillator tunes 455Khz "below" the receive signal, what signal frequency would the tunable oscillator have to be set/tuned to in order to receive WLS, 890Khz, out of Chicago??

What approximate signal frequency would you expect to see at the output of the mixer shown in the video with the receiver tuned to receive WLW, 700Khz, out of Cincinnati, Ohio??

Do you have the RF gain full CW and the Drive control peaked for the VFO frequency setting?

If so should be able to adjust the VFO and see S9 or better Marker signal indication.

Is just the Marker low or off air signals as well? I assume off air as well. Can you inject RF into the SO-239?

Could be lots of issues.
1. Bad molex connection at RF or IF board
2. Open L41 ant step-up transformer
3. Bad or mis-adjusted low voltage supply (9vdc regulated and RF-1)
4. Dirty/bad RL-1 Aux relay contacts

Anytime you have deaf receiver need to break it into basic receiver building blocks.

Low voltage power supplies easy to check with VTVM or DMM. OK to measure at the Audio board TPs to verify that you have 9vdc regulated and 3.2VDC RF-1. However, need to verify it is at where it likes to be used. Just because you have it at its source doesnt mean it is making it to the loads.

Easiest stage to verify good is Audio. If good Audio stage then move on to the IF board. Inject 8.830 RIF and if good then you know problem is on RF board or the path from the SO-239 (in the case of off air signals). Go to RF board and inject actual Rx frequency at TP-1. If dead then inject at Wiper of S1-2. If receiver comes alive then you know L41 is bad.

These are just some examples and not meant to be exhaustive methodology.

With basic test gear (RF sig gen, Audio gen, VTVM etc) can typically isolate problem to a stage in matter of minutes. Then focus troubleshooting at that stage.

Do easy stuff first like wiggling molex connectors.

Best to study the Block Diagram to understand the receiver signal path. Then look at schematic to determine which Molex connectors to wiggle. Short of doing that I guess you wiggle them all. I would not plug and unplug all at this juncture as some would advise.

Hello All,
I am doing more and more repairs lately, and starting to think that I need more test equipment. I'll list below what I have now... I'm thinking that a VTVM is probably a logical next step... No, a fancy service monitor or all-in-one test set is not in the budget:)

What I have:
Fluke 27(Basic DMM)
ESR Meter(Cheap one but it works)
Tek 7704 scope
Leader 70Mhz frequency counter
Heathkit Cantenna Dummy Load
Bird 43
Hong Kong/ebay special sig gen

I am thinking that a VTVM is a logical next step, particularly since a meter with higher input impedence than the fluke seems to be nescessary to fully align the Kenwood hybrids.
 Do you agree? Any recommendations for a specific models?

Concur. Get a VTVM as soon as you can find a decent one in a price you can afford. Invaluable for these radios. Can't take a lot of measurements without one.

A swept signal generator might be next. (You don't mention if it has sweep functions, just that it's a basic Chinese model.) A step attenuator might help along the line for precision calibration, as another thing to think about.

Subject: [TS-520_820_530_830] Test Equipment Shopping

Hello All, I am doing more and more repairs lately, and starting to think that I need more test equipment. I'll list below what I have now... I'm thinking that a VTVM is probably a logical next step... No, a fancy service monitor or all-in-one test set is not in the budget:) What I have: Fluke 27(Basic DMM) ESR Meter(Cheap one but it works) Tek 7704 scope Leader 70Mhz frequency counter Heathkit Cantenna Dummy Load Bird 43 Hong Kong/ebay special sig gen I am thinking that a VTVM is a logical next step, particularly since a meter with higher input impedence than the fluke seems to be nescessary to fully align the Kenwood hybrids. Do you agree? Any recommendations for a specific models? Nathan KK4REY — Sent from Mailbox

There are plenty of Heathkit VTVMs being sold on eBay. Some sellers say, for example, a Heathkit IM-21 is a VTVM. Well it is "sorta". You just have to understand that an IM-21 is an "AC" volt meter that uses vacuum tubes and measures AC voltage. It has no way to measure resistance and DC voltages.

Many VTVM do not come with probes but you can make them yourself. You will need a 1Meg probe when measuring DC voltages but a straight through probe when measuring AC voltages. You can add a 1Meg resistor in some of those Chinese probes by cutting the red lead about 4 inches back from the probe handle and insert a 1Meg 1/2 watt resistor in the probe's wire then cover with heat shrink tubing. Old hollow plastic probes with the screw on nut at the tip are excellent for making probes. I made my 1 meg DC probe using one of those. Simply unscrew the nut at the tip of the RED probe, pull the wire out, then solder a 1meg 1/2 watt resistor to the probe RED wire then feed the other resistor lead through the probes body so it protrude out the tip. When the resistor lead pokes through the tip, pull the lead until the resistor body seats against the probe's end. Cut the lead so the remaining lead can be wrapped around the probe and the nut attached. That's all there is to making a 1meg VTVM probe. I have a 3 VTVMs, 2 Heathkit and one Eico, all analog. I prefer analog VTVMs when perform alignment adjustments, the peaks are much easier to see with an analog meter.

You will need an RF probe. Either the Heathkit 309 RF probe or you can make one yourself, lots of schematics on how to make one can be found on the web. Use "make an RF probe" as your search phrase.

I would find another signal generator, those Chinese generators do not have any way to regulate the signal level. If you use it then I agree with Will, a step attenuator can reduce the signal level. I use a URM-25 and a Heathkit IG-102, they both work very well.

I thought I would only need 1 frequency counter. Wrong!! I found 2 are much better. I use a Sinometer VC-2000 and a Heathkit IM-4100. I needed one to monitor the sig gen output frequency and one to monitor the radio's oscillator frequency, both at the same time.

You should have a couple of lantern batteries, 6VDC found at Walmart, so you can use them as a substitute for loss of +/- 6VDC when needed.

I have a video on my website that shows some basic test equipment I have on my bench.

I thought I included this statement about the Chinese DDS signal generators but I see I left it out.

Those Chinese signal generators have no means of modulating the RF signal and the digital displays are not accurate. I have a few of the Chinese DDS signal generators here and found the digital display would show 7.125Mhz but when I checked the generator's output with my 2 frequency counters, the output frequency was from 2 to 5Khz off frequency. I also have also used an N3ZI DDS VFO as a signal generator in a pinch. It's more accurate then those Chinese DDS generators but again you have to pay attention to the output frequency. I use a N3ZI DDS VFO to control my modified 11 meter Johnson Messenger 223 on 10 meter AM.

Subject: [TS-520_820_530_830] TS-820S wrong frequency on digital display

Gentlemen,
I noticed
some days ago that digital read out of my TS-820S is indicating wrong
frequency on 21 and 28 MHz bands. It is 4 kHz below on 21 MHz and about 10 kHz
below on 28 MHz. However, VFO-dial and xtal-calibration signal are indicating
the correct frequency (btw, matches to reverse beacon results too). Does this
ring the bells to anyone? What would you suggest?

50070. 830S S meter not responding to signals

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-12 22:39:21 UTC
From: rrmvargo@...
Topic: 50070 Message: 50070

Hi All,

I am trying to revive a 1M SN 830S that got smashed. I repaired all the structural damaged and it is looking OK now.

Unit seems to receive well, but no S Meter reading. Meter responds to VR2 & 3, and RF Gain. Does not respond to any received signals or Cal signal. The damage was in the area of the Mic connector & the meter selector switch was undamaged.

For what ever it’s worth, the transmitter is not working. I need to update some cage parts.

Looking at the block diagram, the S signal comes from the IF Amp & RF Amp.
I attempted to search the archives, to no avail. Starting point? Q11 & Q12? Thanx – Bob W8RMV

50071. Re: 830S S meter not responding to signals

Bob

If S meter goes up scale when you turn RF gain pot down then why would you suspect Q11/Q12? Gate of Q11 is hanging on AGC bus all the time. When it sees AGC bus voltage go down when you turn down the RF gain it and the meter driver Q12 drive the meter up scale.

So ask your self what drives the AGC bus voltage down with the off air signal or Marker signal?

Look at last IF amp Q8 and you will see sample of IF signal is buffered by Q9 and then detected by AGC detector diodes D18 and D19. The dc output is used to bias on Q10 AGC amp. Its collector is hanging on the AGC bus and when it turns on it pulls the bus voltage down. So off air and marker signals are detected and used to control the AGC amp which is used as a variable load to pull down the AGC bus to reduce the gain of all the gain controlled devices (is the control or servo voltage for Gate 2 of the dual gate mosfet amps).

So it would seem that the AGC detector diodes and AGC amp are not working. Do you notice a difference when you switch from AGC Slow to AGC Fast?

Not often that AGC detector diodes go bad or Q10 fails but is possible.

Is it possible that AGC switch is stuck in the AGC OFF position? If stuck in OFF strong signals will distort.

Also, need to make sure you have good -6vdc at Conn 3 on IF board and at Emitter of Q10 and anode of D18. The -6vdc is used to back bias the detector diodes to establish the AGC threshold.

Thanx Terry. I am not the expert you are (obviously). I went back & studied the schematic some more & thought the same thing as I looked at Q11/12, but wasn't totally sure. I kinda convinced myself that if Q12 was still good I could get movement from the pots.

Good catch on the AGC, it does not seem to make a difference. The radio is on a compromised antenna in my basement so the AGC not working didn't really stand out. I will investigate the AGC items & the -6VDC you suggest & report back. Thanx again. - 73 Bob

Mike, Nathan,

The Heathkit IM-18 might be a good VTVM choice, at least as a starter.

I found one at a local ham fest about a month ago. Stickered for $10. Paid $5 because the power cord was missing the ground lug, the AC-DC probe lead wires were cracked and brittle and the Ohm adjust pot was frozen. Came with original assembly manual (these are copy write protected now and cost about $20 to buy).

Fixed all issues, including the frozen pot, for no cost with parts on hand. Recapped it with four hard to find caps from wjoe.com for $2.50 plus shipping.

Found a pristine Heathkit RF probe on eBay for $27.50. Total investment <$40 for a like new meter complete with AC-DC and RF probes.

Mark,
  I would steer clear. I looked around and it seems that this meter is for the "CB" gang. There's even a YouTube video from "CB Magazine" showing how to use it. It would probably be fairly accurate on 10 meters, but the other bands, I sincerely doubt it. I mean come on, a meter with a " 0 - 4000" watt scale!

Vacuum tube volt ohm milliammeters, Heathkit brand, kit form when new,
Both of these are the "Bench" type cases, wider than they are tall, with
the meter movement on the left and the function switches to the right.
Both have a bail under the front edge so they can sit tilted toward the
viewer to make it easier to see the reading. They can also be mounted
underneath a shelf or something to keep from using any benchtop space
at all.

Thanks for responding Dave and John.

Yes, as told before, the xtal-calibrator is on the frequency. If the frequency is checked with an accurate signal generator, the display shows wrong frequency indeed. The solder joints and connectors are checked many times before, but haven´t done it once again lately. Thing is: a) the shift is constant and steady b) only on two bands c) the real operating frequency seems to be ok. This seems to me a bit tricky combination. Perhaps this issue sounds familiar to someone in this forum and could lead to find a right solution.

50083. TS-530 Repair

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-13 06:23:44 UTC
From: Nathan Johnson
Topic: 50083 Message: 50083

So this is a different kind of post, I'm not asking for help. I picked up this TS-530S from Craigslist locally. I pulled the covers for a basic safety check before powering. I'm glad I did! I shot two short videos of the checkout.

Part 1:
http://youtu.be/y7xWe434sxw

Part 2:
http://youtu.be/lmQad4KA7Bw

I found the previous owner(s) had made several dubious modifications and repairs.

There were two additional filters installed on a piece of perfboard and pigtailed in place. I am aware that this is a method of installing filters that are not the correct form factor, but in this case the soldering was horrible. I removed them(of course I saved them).

One of the two HV caps had been replaced with a much older/much larger cap mounted upside down. HV wires were pinched and splices not insulated. I replaced this with a good pair from a wrecked 520. I will ultimately replace with new.

Two random wires were soldered to what turned out to be test points on the AF board. I removed them.

The speaker wire(from rear speaker jack to speaker) and speaker were missing. I replaced with parts from the junk 520.

While completing the removal of the filters I found three traces purposely cut on the IF board. I am still consulting the schematic to work out why this was done. I soldered a piece of solder wick across each break.

Some odd, numbered scales had been glued to the front panel behind the drive and load controls. Thankfully these removed easily.

The only remaining problem is that I need a coupler on the band switch shaft. I have one ordered, and once this is in, the radio should be almost complete and just needing alignment. On-air testing has gone well, and it even had a good set of tubes. Not a bad rig for about a C-note and an afternoon's work.

I do have some video shot during the repairs that I may post, but there are plenty of videos of average soldering skills and swapping caps on YouTube, as well as plenty of videos of folks tuning up a hybrid rig. I just figured that somebody might appriciate a laugh at what some people do to these rigs.

I took photos of the cut traces, and I may start a new topic later analyzing that mod. It doesn't appear to match up with any CB mod I could find, one symptom was that the send/recieve switch... Didn't...

Incidentally the filters that I removed were an Inrad #95 and #97... I believe that those belong in an 820? If anybody wants them, make me an offer.

Bob:

I was not trying to criticize you or infer that I am an expert. I learn every day.

I was trying to understand your thought process. All my life I have tried to be a good teacher and a good supervisor. That doesnt mean being your buddy. It means having expectations for you. I was happy you found Q11/Q12.

When I saw that you asked about Q11/Q12 it told me you had looked at the schematic and had enough knowledge and experience to read a schematic. However, I then was puzzled if the meter responds to the AGC bus voltage going down as you turn RF gain pot down why you would think that Q11/Q12 would be source of the problem. Meter circuit cant distinguish between RF gain pot reducing the bus voltage or off air signal or the Marker signal reducing it via AGC detector action.

Take your DMM and measure the AGC bus voltage at Conn 15 Pin 3 (caution Pin 1 is driver tube anode voltage). Notice what happens to receiver background noise level in speaker and notice what happens to the S-meter. Depending on your DMM input Z the noise will drop noticeably and S-meter will deflect up scale. Some DMMs will run indication up to 10 over or more. When this happens you can be assured that Q11/Q12 are working.

Your DMM is having the same effect as Q10 AGC amp. It is placing a load on the AGC bus which by design is a high Z power supply and cannot support any load current.

You might try searching the reflector on AGC bus, AGC detector diodes, S-meter pegged etc to find previous discussions.

Hi Terry,
You are not gonna like this....
So I went in & measured the voltages around Q10 as instructed & indicated on the schematic. Right away I saw that D18 had a "chip" in the glass & thought I had an AHAH! moment, but all voltages at EBC are good. I even measured at the collector & watched that voltage change as I rotated the RF gain. And both diodes checked good. The chip was a manufacturing error I have seen on other glass diodes. So what the heck?? I rechecked the connectors on the board & went back to check the S meter and rotated the AGC knob & Viola!! S meter now works. I call it: "The Laying of the Hands" (or stupid luck). But with your intercession, I did learn more about my radio, and I thank you for that. These inanimate objects just like the human touch sometimes. The cal set signal now gives a good reading, so I can do a quick & dirty alignment check.

Now onto ordering parts for the transmitter, which is a lessor part of the radio for me. It is all about the receiver, although I have been told I sound best on my other working 830. BTW, this 830S has 6146B National Electronics in it. I know they light, but am unsure how well they work. At least one split cap in the cage.

I'll probably be back for more help. Thanx again. - Bob W8RMV

ps-the Fluke 189 only had a small effect on the AGC voltage, which could be heard by the change in the noise floor. I am on other groups, but this group has a handful of true experts. And you are one of the experts here.

50089. Source for wire

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-13 17:32:07 UTC
From: Nathan Johnson
Topic: 50089 Message: 50089

With my current 520 and 530 running well, just waiting on parts order to completely renew the HV sections, I am back to my basket case 820. Much of the point-to-point wiring was damaged in a "high temperature event" on the rectifier board.

Does anyone have a source for an assortment of wire colors of similar size? I'm guessing the neighborhood of 18-22awg, maybe smaller. I would be looking for 6-8+ different colors, 10ft or so each.

Nathan,
Looked at your videos...not the worst I've seen.The filter addition is very common when the owner wants to useFox Tango or INRAD brand filters. Usually they are stuck to anotherinstalled filter with double-sided tape.
  The red and white wires are interesting. I was hard to see but,are/were they connected to the "ground" post" and TP 6?
The cut traces you mentioned may be an after production circuit change.

Yes, that was TP6 and ground. Not sure what they were trying to do there. Don't have my manual in front of me, but that may have been a source of power for some other mod that I did not recieve with the radio.

I know that is a known method of installing filters, would have left them in place if the soldering job had looked better. I may lay out a small PCB to mount the filters in a better way.

The cut traces appeared to be done by a dremel or similar. I will post a picture or two when I get back to my computer this evening. When I first tested, I had no drive, and no RF output. Restoring the traces restored drive and output.

Nathan,
  Any well stocked electronics, or even an automotive or marine supply store will have small spools of various gauges and colors, mostly around 25ft per spool. Radio Shack may have some. I have used in the past pieces of 8 conductor rotor cable to get short lengths of wire for use in repair, and not to forget, similar rigs that are no longer repairable to scavenge connectors and wires.

Date: 2014-11-13 19:37:08 UTC
From: weslugo@...
Topic: 50093 Message: 50093

I will be receiving my new ts520 today or tomorrow, I am a new licensed amateur, I have searched through the manual and online, I am conflicted, should or should I not ground the radio with a 4ft copper rod if my dwelling is less than 10 years old, we do get lighting storms here, AUSTIN TEXAS, I unplug all electric devices in the house when these storms accrue, I am building an antenna and I know that needs grounding. If you would like to share any info with me I appreciate it very much. Again I am a new ham and questions may sound elementary, I wish to be educated by experienced and knowledgeable people. Air time is in the near future after tested equipment, antenna is made and most of all knowledge of the 520.
Thanks Mark KG5ERC

Mark,

You might take some time and read Tom Rauch, W8JI, website on grounding.
Click on the link below

http://w8ji.com/ground_systems.htm

Once Tom's page comes up, select either ground link you want. There are
a few such as Antenna Grounds, Lightning, and House ground layouts you
should read. I have my shack grounds the same as Tom's ground pages show.

My shack is about 80 feet from my house in a 10 x 20 shed (see my
website for a picture). I have a ground rod driven into the ground at
the shack entrance so the breaker panel ground is connected to the
ground rod. The shack ground rod is connected back to the house ground
through a solid copper wire run underground to the house ground rod.
That way the shack AND the house are both at the same ground potential.
I also have a ground rod and my Ameritron RCS4 switch mounted to the
ground rod. A #10 solid copper wire connects both shack ground rods
together.

Mark,
Congrats on getting your ticket. The 520(S) is a solid built rig and you will like operating it.
As far as station grounding goes there are many thoughts...but to save space here go to the groups "Home Page," and just under the picture of
the Kenwood station on the left...click on "conversations" the in the oblong box above...enter "station grounding" and then "search groups"

Why would I not like this?

I asked you if it was stuck in AGC off and had you tried Fast and Slow positions.

I would deoxit the AGC switch. Have to kind of spray at it or can remove the metal meter shield to gain better access and use artist brush to apply it.

Another good source is a control cable from an old LMR radio-

I've used control cables from old GE Delta radios as a source for wire. Just strip off the outer jacket and you can find all kinds of good wire including different gauges, colors and even shielded cable-

I have a video on my website that shows a variety of basic test equipment such as a VTVM, DVM/DMM, Frequency Counter, and Audio generator. Go to my website and click on Videos.

www.w5rkl.com

When the video page comes up, scroll down to the test equipment listing and click on the link. The listing also has a pdf file that lists various DVM/DMM and VTVMs I have with the make and model and specifications listed. Any DVM/DMM you are considering, should have at least a 10 meg input impedance. All the VTVMs and DVM/DMMs I use have 10 meg input impedance.

If you purchase an analog VTVM and it does not have probes, you can make them yourself. The DC RED probe must have a 1MEG internal resistor. I usually make 2 different probes, one for AC which is a straight through, no resistor, wired probe but the DC probe, I installed a 1MEG 1/2W resistor in series with the RED probe wire. If the VTVM has a screw on connector, I changed that to a BNC connector, makes connecting different probes much easier.

You should also have a BNC "T" connector. A BNC "T" connector has 2 female end and one Male end. These come in handy when using a signal generator and a frequency counter together. The frequency counter displays the signal generator's frequency plus allows you to connect the signal generator to the circuit under test at the same time.

You should have a few .01ufd high volt disc capacitors on hand to use as DC blocking capacitors between the signal generator and/or frequency counter and the circuit under test. Not all circuit will have high voltage, just take the time to check with your DVM/DMM or VTVM to determine if the connection point has DC voltage or not. A .01ufd disc cap will allow you to connect a sig gen or frequency counter to the plate of a mixer or other stage with B+ and still allow the sig gen signal or mixer output signal to pass through the capacitor. The capacitor blocks the flow of DC voltage but allows AC sine wave voltage to flow through the capacitor.

TS-530 Repair

Thu Nov 13, 2014 5:37 am (PST) . Posted by:

"Nathan Johnson" jdownj
So this is a different kind of post, I'm not asking for help. I picked up this TS-530S from Craigslist locally. I pulled the covers for a basic safety check before powering. I'm glad I did! I shot two short videos of the checkout.

Part 1:
http://youtu.be/y7xWe434sxw

Part 2:
http://youtu.be/lmQad4KA7Bw

I found the previous owner(s) had made several dubious modifications and repairs.

There were two additional filters installed on a piece of perfboard and pigtailed in place. I am aware that this is a method of installing filters that are not the correct form factor, but in this case the soldering was horrible. I removed them(of course I saved them).

One of the two HV caps had been replaced with a much older/much larger cap mounted upside down. HV wires were pinched and splices not insulated. I replaced this with a good pair from a wrecked 520. I will ultimately replace with new.

Two random wires were soldered to what turned out to be test points on the AF board. I removed them.

The speaker wire(from rear speaker jack to speaker) and speaker were missing. I replaced with parts from the junk 520.

While completing the removal of the filters I found three traces purposely cut on the IF board. I am still consulting the schematic to work out why this was done. I soldered a piece of solder wick across each break.

Some odd, numbered scales had been glued to the front panel behind the drive and load controls. Thankfully these removed easily.

The only remaining problem is that I need a coupler on the band switch shaft. I have one ordered, and once this is in, the radio should be almost complete and just needing alignment. On-air testing has gone well, and it even had a good set of tubes. Not a bad

rig for about a C-note and an afternoon' s work.

I do have some video shot during the repairs that I may post, but there are plenty of videos of average soldering skills and swapping caps on YouTube, as well as plenty of videos of folks tuning up a hybrid rig. I just figured that somebody might appriciate a laugh at what some people do to these rigs.

I took photos of the cut traces, and I may start a new topic later analyzing that mod. It doesn't appear to match up with any CB mod I could find, one symptom was that the send/recieve switch... Didn't.. .

Incidentally the filters that I removed were an Inrad #95 and #97... I believe that those belong in an 820? If anybody wants them, make me an offer.

While completing the removal of the filters I found three traces purposely cut on the IF board. I am still consulting the schematic to work out why this was done. I soldered a piece of solder wick across each break.
Some odd, numbered scales had been glued to the front panel behind the drive and load controls. Thankfully these removed easily.
The only remaining problem is that I need a coupler on the band switch shaft. I have one ordered, and once this is in, the radio should be almost complete and just needing alignment. On-air testing has gone well, and it even had a good set of tubes. Not a bad rig for about a C-note and an afternoon' s work.
I do have some video shot during the repairs that I may post, but there are plenty of videos of average soldering skills and swapping caps on YouTube, as well as plenty of videos of folks tuning up a hybrid rig. I just figured that somebody might appriciate a laugh at what some people do to these rigs.
I took photos of the cut traces, and I may start a new topic later analyzing that mod. It doesn't appear to match up with any CB mod I could find, one symptom was that the send/recieve switch... Didn't.. .
Incidentally the filters that I removed were an Inrad #95 and #97... I believe that those belong in an 820? If anybody wants them, make me an offer.

Re: TS-530 Repair

Thu Nov 13, 2014 10:46 am (PST) . Posted by:

"Nathan Johnson" jdownj
Yes, that was TP6 and ground. Not sure what they were trying to do there. Don't have my manual in front of me, but that may have been a source of power for some other mod that I did not recieve with the radio.

I know that is a known method of installing filters, would have left them in place if the soldering job had looked better. I may lay out a small PCB to mount the filters in a better way.

The cut traces appeared to be done by a dremel or similar. I will post a picture or two when I get back to my computer this evening. When I first tested, I had no drive, and no RF output. Restoring the traces restored drive and output.

Nathan

Bob:

I was not trying to criticize you or infer that I am an expert. I learn every day.

I was trying to understand your thought process. All my life I have tried to be a good teacher and a good supervisor. That doesnt mean being your buddy. It means having expectations for you. I was happy you found Q11/Q12.

When I saw that you asked about Q11/Q12 it told me you had looked at the schematic and had enough knowledge and experience to read a schematic. However, I then was puzzled if the meter responds to the AGC bus voltage going down as you turn RF gain pot down why you would think that Q11/Q12 would be source of the problem. Meter circuit cant distinguish between RF gain pot reducing the bus voltage or off air signal or the Marker signal reducing it via AGC detector action.

Take your DMM and measure the AGC bus voltage at Conn 15 Pin 3 (caution Pin 1 is driver tube anode voltage). Notice what happens to receiver background noise level in speaker and notice what happens to the S-meter. Depending on your DMM input Z the noise will drop noticeably and S-meter will deflect up scale. Some DMMs will run indication up to 10 over or more. When this happens you can be assured that Q11/Q12 are working.

Your DMM is having the same effect as Q10 AGC amp. It is placing a load on the AGC bus which by design is a high Z power supply and cannot support any load current.

You might try searching the reflector on AGC bus, AGC detector diodes, S-meter pegged etc to find previous discussions.

w8rmv
Terry,
No offense taken. I am self taught & I had a bad teacher (as the saying goes). I am relatively new to the 830S & new to the repair process itself compared to yourself & others. I also know that if I don't first try looking at the SM, I will be told to do so. ;-) I come here, after I get lazy and/or run out of competence. Thanx again for the help & I will get back in a few days. I've a Fluke 189, but I think one of my FET analogs has a 20Mohm input on some ranges. The AGC comment was a big help & something I missed & should have caught. - 73 Bob Reply to sender . Reply to group . Reply via Web Post . All Messages (6) . Top ^

Hi Terry,
You are not gonna like this....
So I went in & measured the voltages around Q10 as instructed & indicated on the schematic. Right away I saw that D18 had a "chip" in the glass & thought I had an AHAH! moment, but all voltages at EBC are good. I even measured at the collector & watched that voltage change as I rotated the RF gain. And both diodes checked good. The chip was a manufacturing error I have seen on other glass diodes. So what the heck?? I rechecked the connectors on the board & went back to check the S meter and rotated the AGC knob & Viola!! S meter now works. I call it: "The Laying of the Hands" (or stupid luck). But with your intercession, I did learn more about my radio, and I thank you for that. These inanimate objects just like the human touch sometimes. The cal set signal now gives a good reading, so I can do a quick & dirty alignment check.

Now onto ordering parts for the transmitter, which is a lessor part of the radio for me. It is all about the receiver, although I have been told I sound best on my other working 830. BTW, this 830S has 6146B National Electronics in it. I know they light, but am unsure how well they work. At least one split cap in the cage.

I'll probably be back for more help. Thanx again. - Bob W8RMV

ps-the Fluke 189 only had a small effect on the AGC voltage, which could be heard by the change in the noise floor. I am on other groups, but this group has a handful of true

experts. And you are one of the experts here.

Source for wire

Thu Nov 13, 2014 9:46 am (PST) . Posted by:

"Nathan Johnson" jdownj
With my current 520 and 530 running well, just waiting on parts order to completely renew the HV sections, I am back to my basket case 820. Much of the point-to-point wiring was damaged in a "high temperature event" on the rectifier board.

Does anyone have a source for an assortment of wire colors of similar size? I'm guessing the neighborhood of 18-22awg, maybe smaller. I would be looking for 6-8+ different colors, 10ft or so each.

Nathan,
  Any well stocked electronics, or even an automotive or marine supply store will have small spools of various gauges and colors, mostly around 25ft per spool. Radio Shack may have some. I have used in the past pieces of 8 conductor rotor cable to get short lengths of wire for use in repair, and not to forget, similar rigs that are no longer repairable to scavenge connectors and wires.

Ts520 ?

Thu Nov 13, 2014 1:18 pm (PST) . Posted by:

weslugo
I will be receiving my new ts520 today or tomorrow, I am a new licensed amateur, I have searched through the manual and online, I am conflicted, should or should I not ground the radio with a 4ft copper rod if my dwelling is less than 10 years old, we do get lighting storms here, AUSTIN TEXAS, I unplug all electric devices in the house when these storms accrue, I am building an antenna and I know that needs grounding. If you would like to share any info with me I appreciate it very much. Again I am a new ham and questions may sound elementary, I wish to be educated by experienced and knowledgeable people. Air time is in the near future after tested equipment, antenna is made and most of all knowledge of the 520.
Thanks Mark KG5ERC

Mark,

You might take some time and read Tom Rauch, W8JI, website on grounding.
Click on the link below

http://w8ji.com/ground_systems.htm

Once Tom's page comes up, select either ground link you want. There are
a few such as Antenna Grounds, Lightning, and House ground layouts you
should read. I have my shack grounds the same as Tom's ground pages show.

My shack is about 80 feet from my house in a 10 x 20 shed (see my
website for a picture). I have a ground rod driven into the ground at

the shack entrance so the breaker panel ground is connected to the
ground rod. The shack ground rod is connected back to the house ground
through a solid copper wire run underground to the house ground rod.
That way the shack AND the house are both at the same ground potential.
I also have a ground rod and my Ameritron RCS4 switch mounted to the
ground rod. A #10 solid copper wire connects both shack ground rods
together.

Mark,
Congrats on getting your ticket. The 520(S) is a solid built rig and you will like
operating it.
As far as station grounding goes there are many thoughts...but to save space here go to the
groups "Home Page," and just under the picture of
the Kenwood station on the left...click on "conversations" the in the oblong box
above...enter "station grounding" and then "search groups"

820s digtal display broken

Thu Nov 13, 2014 1:19 pm (PST) . Posted by:

j.marmann
Hi,

I have a 820s with cracked digital display tube. I found one at ebay for 100€, is that an acceptable price? Are there other options like installing a 3rd party display?

Juergen

please remember to properly sign your msgs/posts.. .. name and call(if any). 73 Joe wb7uqu

Thanks Mike,W5RKL,

I just saw this reply this morning Nov 14. and I am taking a look at the videos now. Thanks for the homework!

Thanks to Neil VK6NSB also for the info on the DD-103, I saw your pictures, looks good.

I asked the xyl for one one Christmas. well see if I get it, Hi Hi

I figure if I do, and eventually get an external VFO I can switch back and forth if I need to operate split.

From: taylorfrank13@...
Topic: 50109 Message: 50109

Hello , new member here with a 830s display problem.
Display works great but on occasion does not change
with rotation of the vfo knob. It stays at 3000, 65000,
ect depending on the band selected. I can move the rig or beat on it
(caveman style) and it reverts to normai.
I have grounded boards, done the star washer thing , removed all
board connectors but still have the problem. It appears that the display
does not receive a signal form the vfo intermittently. Which connector
carries the vfo signal to the display? which board do i need to check for
solder joint integrity/
Thanks, Frank aa4ex

Instead of beating on it you might try exercising the FIX switch multiple times!

Wonder why KW engineers didnt think of star lock washers?

Topic: 50109 Message: 50111

I forgot to mention if the display is reading 500khz low on all bands then most likely you have lost the "CON" signal from the PLL board to the Digital Display board.

Can try wiggling Conn 3 of the PLL board or gently pulling/pressing on the lead wires entering the plug body. Best if you have an O-scope to measure the CON signal.

Also from time to time I find bad solder connection on Jumper J1 (small grey coax) on the PLL board that brings the VFO signal to Mixer Q29.

For example normal CON readings on 40 meters for ends and middle of VFO travel is as follows:

7.500 = 1.000mhz
7.250 = 0.750mhz
7.000= 0.500 mhz

The level will be approx 375mv P-P or 125 mv rms.

Waveform is a sine wave with nice rounded top half and sharper bottom half of the cycle.

CON is the same as Cin on the TS-820S.

Terry K9TW

Update, got home after work last night to find my TS520 at the fron door , I opened the heavy and rather large box to find it was packaged fairly well bubble wrap and Styrofoam in a heavy cardboard box, I then opened it pulled it from its nest, I placed it on my computer desk and began to inspect it, I noticed the white indicator lines on the all the knobs were brown, I can clean them, no biggie, the meter glass/plastic was clean and no cracks, I than looked to see that the top and btm screws had been removed before, ok that's fine too, I pulled the covers and to my surprise I noticed both the SSB and CW crystals were both there, (the person that sold it to me did not know if both were there), to me it does not look like any work has every been done to it, I dusted it off with a soft brush, I noticed the wire for the external speaker jack in the back need to be soldered and on the noise blanker board the negative wire was off, don't know why, looks deliberate, have not powered it up yet, and I need an antenna,(I am a newly licensed amateur ham operator) I am going to start building my antenna this weekend. I will take pics of the 520 and post later on. Talk to you later. Mark KG5ERC

Subject: [TS-520_820_530_830] Ts520 Received

Update, got home after work last night to find my TS520 at the fron door , I opened the heavy and rather large box to find it was packaged fairly well bubble wrap and Styrofoam in a heavy cardboard box, I then opened it pulled it from its nest, I placed it on my computer desk and began to inspect it, I noticed the white indicator lines on the all the knobs were brown, I can clean them, no biggie, the meter glass/plastic was clean and no cracks, I than looked to see that the top and btm screws had been removed before, ok that's fine too, I pulled the covers and to my surprise I noticed both the SSB and CW crystals were both there, (the person that sold it to me did not know if both were there), to me it does not look like any work has every been done to it, I dusted it off with a soft brush, I noticed the wire for the external speaker jack in the back need to be soldered and on the noise blanker board the negative wire was off, don't know why, looks deliberate, have not powered it up yet, and I need an antenna,(I am a newly licensed amateur ham operator) I am going to start building my antenna this weekend. I will take pics of the 520 and post later on. Talk to you later.

Terry, You nailed it, TP1 has almost no solder and came loose when I tugged on it.
That was my intermittent. Display and VFO are communicating. We are so
fortunate to have such skilled people as you on this board.
Another problem if you may. The output on the lower bands is 60 watts ,
on upper bands 100. Plate current is 250mils. I sprayed the bandswitch
and exercized it to no effect. Also the radio had no cover on the RF cage.
Should i get a cover? Guess rig has been altered. Anything easy I can check?
The finals look original and driver gives S9 signal 10mtr calibration.
Thanks
Frank

FYI, If your 830 has intermittent VFO display connection that causes the display to stay on a frequency 500kc lower than the band your are tuned to and does not change with changing vfo frequency, as per Terry's advice check the PLL board for solder connection at TP1 and J1. Mine was loose . Also check connector 3 on PLL board.

50123. Kenwood TS-530S Normal Operation video

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-15 20:56:33 UTC
From: louis.wilen@...
Topic: 50123 Message: 50123

Mainly for the benefit of hams who have acquired a TS-530S or similar Kenwood hybrid rig, I have posted a 17 minute video to YouTube that shows normal operation of the rig's controls, meter, and indicator lights.

The video is at:
Kenwood TS-530S normal operation https://www.youtube.com/watch?v=3tfTT69BMw4

https://www.youtube.com/watch?v=3tfTT69BMw4

Kenwood TS-530S normal operation https://www.youtube.com/watch?v=3tfTT69BMw4 This feature is not available right now. Please try again later.

View on www.youtube.com https://www.youtube.com/watch?v=3tfTT69BMw4
Preview by Yahoo

Hopefully this reduce confusion as to what is normal vs. when there is an actual problem with this rig.

Perhaps folks with the other Kenwood hybrid rigs could make similar videos.

Nice video, Louis. I heard you mention it this afternoon on the Kenwood Hybrid Net and checked it out. It fills a missing niche, I think. We've got users on here who like to tinker and rebuild, and then we've got newer hams seeking to use a Kenwood Hybrid for their first HF rig.
Your video does a good job of showing them what the rig is supposed to do - simulating an Elmer!

The following is a cut and paste response from Osamu Hazawa, a member of this group since 12 Oct 2005, from a discussion about the TS-520D, dated 17 Sept 2009. He states he owns a TS-520D and it has 2 final tubes and produces 100 watts output.

"Hello All,

I don't know the TS-520D was introduced to the market other than in Japan,
TS-520D is 100W version of TS-520X (10W, vice versa).
I own an TS-520D and it has 2 final tubes installed.

Osamu"

Hello Louis,

I enjoyed the video for the Kenwood TS-530S, I purchased a TS530s as my first radio. I have had for about 6 months and this video helped to sort out some things I did not quite understand. I have been using it on 40M and 20M mostly, today I tries it on 15 meters.
I have a question if you do not mind. On the other bands my SWR is around 1.5:1 when I transmit, but in 15M it jumps way up to over 4:1. I have a G5RV at 35 feet going into an MFJ-949E tuner and I follow the tune procedure from the manual and the SWR in tune up is 1.1:1 do you have any ideas what might cause this?

Thank You
Greg K8ult

What kind of Wattmeter/SWR meter are U using ? If it is the kind with a calibrate SWR switch and Sensitivity knob you have to set , are you recalibrating it on 15M when you changed bands ? Those old meters are more sensitive to SWR readings on the higher bands.You have to reset them for each band change.I have the MFJ948 And the SWR readings are pretty reliable,I don't know what metering the 949 has.Worse case is you have a connection somewhere between the radio and antenna that is arcing over on 15M when you increase power from tune level to normal operation. I had this happen when I had a wet connection on one of my antennas. My radio is Ham Radio...CW is Real Radio

A small correction. The "D" model was being used in Japan and Korea. I had one of them too. Its power output was 100W (not 50W). When I saw the "S" model when I came here, I thought it would be almost identical to the "D" model except it is Kenwood.

Bob,
L-41 or the "antenna step-up transformer" is pure gold. It has been unavailable as a Kenwood part for quite sometime. If you can not findsomeone who has a junk RF board..with a good L-41, the only other choice is to rewind it yourself. Gordon-n6wk(SK) a long time member of this board used to rewind them, but he's gone now. There's a good drawing done by Gordon in the "files" section of this board, regarding the rewinding of L-41. 73 Joe WB7UQU

50135. Hybrid Net Update (November 16, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-16 22:23:35 UTC
From: Mark Gilger
Topic: 50135 Message: 50135

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There were 23 stations checking in under good band conditions.

We had the following number of radios checking in.

4 running TS-520(x)
8 running TS-530(x)
5 running TS-820(x)
4 running TS-830S
0 running TS-511
0 running 599 twins

I was running my Drake 'C' liine & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were 20 stations checking in under fair band conditions. He had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
5 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S & Drake L4B amplifier.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 68, Sunday☐s total = 58 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

Bob,

Make sure you have a look at Q1 3SK73GR, these are available in Toshiba brand relatively cheap if you have to go down that path.

Need an L34-2004-05 coil for the Kenwood TS-830S.

It is L41 on the RF board.

Anyone have such a beast?

Greg,

Thank you -- and others -- for the kind comments about the video.

If I understand correctly, you are tuning up into a dummy load (as you should) on 40, 20 and 15 meters and the SWR is nearly 1:1. That indicates that the high SWR is caused by factors outside of the rig, such as the tuner, the feedline, and the antenna.

I’ve never used a G5RV, so I can’t give any first-hand advice specific to that antenna. You might look at http://www.w8ji.com/g5rv_facts.htm for some tips. The high SWR appears be normal for this antenna according to what I’m reading.

Without going into too many details on this forum (since the focus is the Kenwood hybrids, not antennas), I’ll say that you should mainly be concerned about the amount of RF power actually radiating from the antenna. The SWR measured at the antenna side of the tuner is not that important when your feedline loss is low – and the feedline loss will be lowest by keeping the coax from the tuner to antenna short and by using reasonably low-loss coax such RG-213 (or better), not RG-8X or RG-58).

What kind of Wattmeter/SWR meter are U using ?
If it is the kind with a calibrate SWR switch and Sensitivity knob you have to set , are you recalibrating it on 15M when you changed bands ?
Those old meters are more sensitive to SWR readings on the higher bands.You have to reset them for each band change.
I have the MFJ948 And the SWR readings are pretty reliable,I don't know what metering the 949 has.
Worse case is you have a connection somewhere between the radio and antenna that is arcing over on 15M when you increase power from tune level to normal operation. I had this happen when I had a wet connection on one of my antennas.

Subject: [TS-520_820_530_830] Re: Kenwood TS-530S Normal Operation video

Hello Louis,

I enjoyed the video for the Kenwood TS-530S, I purchased a TS530s as my first radio. I have had for about 6 months and this video helped to sort out some things I did not quite understand. I have been using it on 40M and 20M mostly, today I tries it on 15 meters.
I have a question if you do not mind. On the other bands my SWR is around 1.5:1 when I transmit, but in 15M it jumps way up to over 4:1. I have a G5RV at 35 feet going into an MFJ-949E tuner and I follow the tune procedure from the manual and the SWR in tune up is 1.1:1 do you have any ideas what might cause this?

Thank You
Greg K8ult

Greg and others:

There is a lot of information and misinformation on the internet and even in some books about SWR, reflected power, and its effect on rigs and stations. Here is an article from Advanced Energy Industries (http://www.advanced-energy.com/) about reflected power that is clear and accurate, and even explains the real reason that the plate of tube gets extremely hot when reflected power (and SWR) is high.

Forward and Reflected Powers. What Do They Mean?

Ian,
It's easier if you take the bottom cover off the rig too, and remove the four(4) screws that hold the DG-1 in. They are along the FIX-VOX board. PLEASE do this with rig disconnected from all power. That way you can get real good access to the boards for cleaning the connectors/pins as a first step. This may solve you "wonky" complaint. The next step would be to rework the 18 or so "through holes" or "vias" they also over time can cause problems. Kenwood even put out a service bulletin on it

Hello Greg,

I have a G5RV-Jr, and the one band that I cannot load it up on is 15 meters. If you can load your TS-530S normally into a dummy load on 15 meters than I suggest it may be the antenna. Even with my MFJ tuner, I cannot get the G5RV-Jr to load without very high SWR on 15 meters.

Thanks Joseph. I found that the VFO switch (lower RHS) to be very noisy and intermittent. So, before taking out the DG-1, I gave it a good shot of contact cleaner with the lower cover off - cycled the switch a few times, waited 10 minutes for the solvent to flash off, and it works perfectly. Tried it again this morning, good on all bands.

I will see how it goes over the next few days.

Thanks

Ian

I guess i forgot to put my signature on my last response, so it was rejected.

lets get back to the topic of L41.... here is another copy of my last message

Hi Joe,

tnx - the coil itself is good, the core is broken (bonehead me broke it trying to move it just a bit farther - couldnt quite get peak... dohhhhhhhh).

L41 is on 1.8 mhz - does it really affect the other bands? i dont need much gain on 160 with the noise floor i have.

ya, i figgered any of the coils/cans are made of Unobtanium by now... just thought someone may have a stash.

im still getting -107 dbm for 0db of audio on a HP400FL with
8.2 ohm dummy for the speaker, HP8648 for SigGen as seen below.

all values based on 0 db on HP-400FL AC voltmeter with load as above. Volume control on radio for this is about 9:20 on the dial.

Band dbm
1.9 -107
3.75 -111.8
7.15 -108.9
10.125 -105.1
14.175 -108.8
18.125 -110.2
21.225 -96.4
24.95 -116.1
28.8 -112.3

but i dont have any frame of reference for if these numbers are "good" or not.

note how dead 15 meters is relatively - yet the cans peaked out fine. Suggestion?

S/N is 7050063, built in mid '86 based on date codes on random parts.

will do MDS check soon (if i remember how), and have yet to sweep the IF response...

incidentally, i noticed that the audio begins flat topping after 1/2 volume is this typical? at 1 o'clock on the knob its really clipping, but this isnt normal volume level either.

i cant tell you enough of how useful this group has been, and the various kenwood hybrid sites have been - its invaluable !!

Hi, Greg.

I have two "juniors" (one bought and one home-brew) that I use with my 820S and used my RigExpert AA-54 to scan them over all the bands (including the feed lines). How the antennas act depends on a lot of factors, but mine only had lower SWR (2:1 or less) on 40, 10, and 6 meters. SWR on 20 and 15 are pretty high, but match-able with a tuner--I use an AT-600 Pro II. I was a little surprised that 40 was better than 20, based on what I've read. Mine are both in attics and I have been quite pleased with them, but always assumed you need a tuner with them.

Date: 2014-11-17 17:02:33 UTC
From: kb3dxr@...
Topic: 50147 Message: 50147

I have been a lurker here for quite some time and this is my first post. I picked up a long idled TS-520s at a local ham-fest a few years back. I have finally replaced the HV caps, screen and driver caps and attempted to power it up for the first time last night. Since it is my intention to only test the receive portion of the radio at this time, I had the filament and screen voltages turned off. Initial results are that the internal speaker is dead, there is a hum on the audio, it is difficult tuning in stations, and when I am able to, the voices sound metallic, like highly compressed digital audio. When I switch on the 25kHz marker, it appears across the band but it sounds like a buzz-saw and not a solid tone.

I have not replaced any other electrolytic caps at this time and only replaced the ones previously mentioned over concerns of damaging the radio at power-up if they had failed. Would the electrolytic caps on the rectifier board cause hum on the audio if they have dried out? Should the 25kHz marker sound like a solid tone?

73,

Christopher KB3DXR

Hello Dondi,

The TS-830 has a wide microphone impedance range from 500 ohms to 50K ohms. A typical D-104 microphone has a high impedance and will work fine with the TS-830, no changes required to the microphone or the TS-830. If the D-104 is the amplified microphone you should keep the microphone volume level (adjusted on the bottom of the stand) to a low level and the TS-830's MIC gain set so the ALC peak indication during normal sideband transmissions is within the ALC meter scale. It's very easy to over drive the TS-830 speech amplifier. Also, do not use the TS-830s audio processor with an amplified D-104 microphone.

Bob:

Here are my TS-830S results from a pretty well aligned rig and one just coming in the door.These are with 8.2 ohm dummy load and using a HP3400A reading the 0dB level (peaked with the VFO and the Drive Control). Also have the AF gain at approx 9:30 and the Tone control full CW or full treble. Mode CW. Using a calibrated Wavetek 3002 RF sig gen.

1.900 = -121.5 dBm
3.750 = -120.7 dBm
7.150 = -118.8 dBm
10.125 = -115.9 dBm
14.175 = -120.6 dBm
18.125 = -119.5 dBm
21.225 = -119.0 dBm
24.950 = -121.3 dBm
28.800 = -117.9 dBm

1.900 = -113.6 dBm
3.750 = -113.8 dBm
7.150 = -114.4 dBm
10.125 = -109.2 dBm
14.175 = -113.5 dBm
18.125 = -113.7 dBm
21.225 = -113.9 dBm
24.950 = -118.5 dBm
28.800 = -115.1 dBm

You might try contacting Dick Housden at W0NTA.Com. He may have some rewound L41s that he would be willing to sell. I have a couple but simply cannot let any go as I need them for customer radios. I usual wind two or three to get one good one. Eyes and hands arent what they use to be!

As for 15 meters. You may have bad Ant/Mixer bandswitch contacts? Is RF drive and output good on 15 meters? Test Drive with SG switch off in CW mode and see if you can get FSD ALC indication and how much Car Level does it take in contrast to other bands.

Terry K9TW

Hi Terry,
Nice comparison.
Next time you align a TS820, would you kindly record the same for reference?

For clarity :

"...8.2 ohm dummy load..." typo?

"...well aligned rig and one just coming in..."
Is the first table from the incoming rig? (higher negative dBm)

Mark; before you put that old TS-520 in the transmit mode, be sure that the antenna output is into a dummy load! It can save your 3 expensive tubes! I have a TS-520 and a TS-820S, nice old radios, but they take care in tuning them up and getting them on the air. 73, de KO8S, Karl

Well after one night of fun listening to CQ Contest I turned on the 520 tonight tuned it up was listening to aukward noise like in a tunnel coming from radio, than all the sudden darkness to the transceiver and a smell like an old basement, so here is some more fun, yes fun, it was nice just listening to the contest but now I get to delv into another aspect of amateur radio, funny I still need experience building antenna. I will replace fuse and order some new final to start. Sg switch is ok. Any advice let me know, if not I will keep you posted on my progress. Oh by the way, I was able to snag a Heathkit Im28 this weekend online. Thanks. Oh yea one more thing I never even made contact with anyone. HA:)))Mark KG5ERC

Hi Dave:

Hard to find a 8.0 ohm power resistor but can make one from a series/parallel combo. Easy to find a "sand" type 8.2 ohm power resistor. Mine is a a Dale 20 watt unit I had in the junk box. Not critical to be precisely at 8.0 ohms. Just best to use 8 ohm dummy load on ext speaker jack so you dont rattle or destroy your little 3 inch speaker in the rig when doing these kinds of measurements.

The higher the negative dBm number the lower the uv signal level. Higher is better. A good functioning and well aligned TS820 or TS830 will have a noise floor of approx -136dBm or so. This number varies with the band due to atmospheric noise differences so I typically take it on 20 meters for comparison reasons. I always measure the as found and as left MDS on all hybrids that I service. Minimum Discernable Signal level is the signal level required at the SO-239 to produce an output that is 3dB above the noise. It is normal to do this measurement in CW mode at approx 500hz bandswidth.

I previously posted on this forum how average ham with a analog VTVM with a dB scale on it can easily measure the receiver noise gain. I dont remember the Message number but can find this procedure by Googling. Rob Sherwoods power points from Dayton Hamfest usually always cover it as well. I would look at 2010 and 2011 presentations.

Surprisingly some techs who work on these radios for a living dont understand how to do these measurements and dont have a calibrated RF signal generator. Because of all the strong signals on the air they just do a rough alignment using the S meter and call it good enough and the average owner wont know the difference unless they can do some AB testing between rigs on same antenna and same weak off air signals.

Terry,
tnx much for the comparison data... this gives me a framework for a perspective. I'm going to squirrel that away for reference. also tnx for the reference for Dick H.

yes i'v gone thru the bandswitch twice now, cleaning contacts etc... and had to pull the RF board to fix broken solder connections on the bottom side of the board on the driver tube socket.

My L41 is good, but the slug is cracked. i assume the broken coil slug on the 1.8 only really affects 160m.. its down about 8 db from peaked before bonehead me snapped it !!

since that band doesn't require peak gain, i can live with it if i cant find one... my noise floor on 160 far exceeds the rx capabilities, and i use the attenuator normally anyway on that band.

what is the equation used for the Kenwood db numbers to dbm conversion that you used in the table that you made (tech note i downloaded) ?

dave, the 8.2 ohm was a dummy load for the Speaker/audio outputs... NOT for the xmtr.

Mark,

You said you were going to replace the fuse and order new final tubes. Why are you ordering new tubes when you have no idea what caused the fuse to blow in the first place???

Unless you know for sure, based on results from troubleshooting, that the tubes are at fault then you are, at this point, guessing at the source of the problem plus you are wasting time and money that more than likely will not fix your problem!!

I recommend you set the SG switch to OFF, set the HEATER switch to OFF, replace the fuse with a correct rated fuse (6 amp for 120VAC), then power up the 520. If the fuse blows right away then the tubes are more than likely NOT the source of the problem.

50159. Powering up LV DC

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-18 19:35:30 UTC
From: roberteleazer@...
Topic: 50159 Message: 50159

I have a TS-520 with a blown (as in actually smoking) power supply board that I am going to resume trying to repair. The previous owner had a serious power supply problem and disconnected all of the power supply leads and tacked them back together with jumper wires, presumably so he could isolate which section was causing the power supply problem.

I have replaced the power supply board with a rebuilt one and I have been replacing all of the caps and tracing where the disconnected power supply wires go. I have not found any caps that were exploded or even shorted, but I have found some that have a very rapid decay time after being charged up.

I thought I would try powering up just the low voltage DC section using an external power supply and see how that works. Have any of y'all tried that approach and do you have any recommendations on it?

Thanks!

Robert: If you have not already done so, I would start at the power transformer, all windings disconnected. It is possible that one or more windings may have been damaged. If you are not sure what to do, just e-mail.
Usual warnings about high voltage apply, and I would suggest a resistance test first when all windings are totally disconnected. This will let you know if there are any open windings or dead shorts. I don't know what proper readings in ohms for the several windings are, but I would think that HV would be the highest, followed by the primary. Even the filament windings should have some resistance. Once you are certain about any shorts, then you can test for proper voltages.
Good luck
Bob WA2JAJ/4

Bob:

I am pretty sure I posted on this forum before the formula for the dB to dBm conversion chart I developed, but not always easy to retrieve. Maybe it was on another forum?

Remember KW uses the odd ball reference 0.50uv = 0dB and not 1.0uv. You need a calculator with Anti-log key. If no Anti-log key it may have a 2nd key.

Here in America most RF sig gens output attenuators and panel meters are labeled in UV (microvolts) and/or most commonly in dBm. Apparently in Japan the signal generator output is in dBu?

Here is an example:

A KW hybrid service manual tells you to inject an 8dB signal (common for S meter cal). How many UV = 8dB? and How many dBm is that?

1. 8 = 20 log X / 0.50
2. 8/20 = 0.4 = log X/ 0.50
3. Anti-log of 0.40 = 2.512
4. (0.50)(2.512) = 1.2559uv
5. 8dB = 1.26uv

When the service manual tells you to inject 8db you now know to set your step attenuator for 1.26uv output.

There are numerous online calculators and spread sheets that convert from Uv to dBm. 1.26uv = -105 dBm. If you dont have spread sheet or calculator and want to calculate it then do this:

To go the other way use 224mv = 0 dBm reference

1. X dBm = 20 log 1.26uv/224mv
2. 1.26 x 10 to -6 / 224 x 10 to -3 = 5625 x 10 to -9 or 0.000005625
3. Log of 0.000005625 = -5.2499
2. (20)(-5.2499) = -104.997
3. 1.26uv = -105 dBm

I had an unreadable digital display on the bands above 20 meters ever since I purchased the used rig a few months ago. So today I finally got around to removing the digital display module & tore into it. Removed both circuit boards and gave all contacts a good scrubbing with Deoxit. Burnished the 3 circuit board ground points on one of the boards, reassembled and tested. Display works great now!

It can be done very easily! Just be patient and careful when removing the boards from it's chassis and the connecting pins.

Yep, I have done that. I disconnected all the wires coming from the power supply board and noted the smoke that resulted when powered up. I noted that the board itself was smoking and while I saw some evidence of smoke affecting the case saw no other burned areas. I checked the voltages at the power transformer and found them Okay.

I also noted that for some reason someone had disconnected the large HV filter caps and hooked them directly to the HV AC with no diodes in between (!!) I don't know if this was an error or some strange form of troubleshooting but I am glad I found that before powering it up for the first time.

I have been doing other things for the past several months and I hope to finally get back to work on the set tomorrow.

By the way, if Mike W5RKL is still collecting old power supply boards I may have one for him.

Thanks,

Dave:

Per your request:

I have 3 TS-820s rigs here now and just starting on one that owner reports has no RF output but no known receiver issues. Of course I appreciate what the owner reports but I always reserve judgement on that feedback. Each mans definition of quality differs. Reasonably accurate measurements takes subjectivity out of it.

I once had a customer complain about how noisy his receiver was when he got it back. He stated that before it was very quiet and signals just seemed to suddenly jump out at him as he tuned across the bands. I wrote back and explained what the RF gain pot and RF attenuator was for and that he was formerly primarily listening to operators running power and using gain antennas. He wrote back and said he didnt care if he couldnt hear "QRP" stations! I told him how to turn his RF-1 voltage down to reduce the AGC bus voltage and reduce the gain of the IF and RF gain controlled devices. He was happy again!

I repeated on USB as not certain if you have CW filter or not? These were taken with the AF gain pot at approx 9:30 or half way between #2 and # 3 position.

CW

1.900 = -113.5 dBm
3.750 = -115.2
7.150 = -112.6
14.175 = -112.9
21.225 = -112.5
28.800 = -112.2

SSB

1.900 = -114.4 dBm
3.750 = -116.3
7.150 = -114.7
14.175 = -115.2
21.225 = -113.5
28.800 = -114.2

If you are not certain here are the corresponding uv levels involved.
-112dBm = 0.560uv
-113dBm = 0.506uv
-114dBm = 0.446uv
-115dBm = 0.398uv

Hello to group, just replaced the band switch coupler with a solid brass one and all is well. However, I noticed for the first time that the band switch has no left and right stop. The switch rotates 360 degrees. Is this correct? I never paid any attention to this before so was wondering if I hosed something when replacing the coupler. Thanks, Steve K0SJS

Frank,

What "interface" are you referring to?

Have you been told you need an amplifier interface to connect your TS-820 to your AL-811H amplifier? If so, don't believe any of that non-sense!! You do NOT need an amplifier interface to connect your TS-820 to your AL-811H amplifier!!

All you need is an 8 pin octal plug which can be found on eBay or other sources. The cable can be simple shield cable found in DVD/VCR player/recorder boxes. Simply cut one end off leaving the RCA plug on the other end. Connect the cut end as follows, one cable for the amplifier's RELAY and one for the amplifier's ALC connection.

1. ALC connection. Strip the covering off the cut end of the cable. Connect the center wire to pin 6 and the shield (ground) to pin 1 or 4 on the 820's 8 pin plug.
2. RELAY connection. Strip the covering off the cut end of the cable. Connect the Center wire to pin 5 and the shield to pin 1 or 4.

Plug the RELAY Cable RCA plug into the amplifier's rear panel RELAY socket.
Plug the ALC Cable RCA plug into the amplifier's rear panel ALC socket

That's ALL you have to do!!!!

READ the AL-811H amplifier's manual and perform the amplifier's ALC adjustment as outlined in the amplifier's manual!!!

The AL-811H relay voltage is 12VDC at approximately 100ma when the relay is energized. The amplifier relay terminal (N.O. "Normally Open" terminals pin 5) in the TS-820 can easily handle that DC voltage.

From: Mike W5RKL
Topic: 50178 Message: 50181

Actual Karl, the SB-200/220 and the SB-201 and SB-221 Heathkit amplifiers have a much higher relay voltage, approximately 110VDC.

If you have any doubt as to what an amplifier's relay voltage and current is, you can use a DVM/DMM to measure the amplifier's relay voltage and the amplifier's relay current. Most DVM/DMMs have a voltage overload protection circuit, read the DVM/DMMs manual for details.

To measure the amplifier's relay voltage:

1. Set the DVM/DMM to measure DC voltage, set to 200VDC to start.
2. Connect the DVM/DMM's "RED" probe lead to the amplifier's relay socket's center terminal and the DVM/DMM's "BLACK" lead to the amplifier's chassis.
3. Switch the amplifier ON and set the STBY/OPR switch to OPR and read the amplifier's relay voltage on the DVM/DMM. IF necessary change the DVM/DMM's DC voltage level setting to a lower DC level until you see the approximately relay DC voltage.

To measure the relay's current level:

1. Change the DVM/DMM to measure "current", typically requires moving the DVM/DMM"s "RED" probe to the DVM/DMM's "20A" or "mA" socket.
2. Connect the DVM/DMM RED probe to the amplifier's RELAY socket's center terminal and the DVM/DMM's BLACK lead to the amplifier's chassis.
3. Connect the amplifier to a 50 ohm dummy load, do NOT apply any RF drive.
4. Set the amplifier's STBY/OPR switch to STBY
5. Power up the amplifier, the amplifier's relay should NOT energize.
6. Switch the STBY/OPR switch to OPR, the amplifier's relay should energize. Read the amplifier's relay current on the DVM/DMM.
7. Set the amplifier's STBY/OPR switch to STBY, amp's relay should de-energize. Power down the amplifier.

That's all there is to measuring an amplifier's relay voltage and current.

You should read the transceiver's operator's manual section that discusses connecting the transceiver to an amplifier. This is especially important if you are connecting a solid state transceiver that has an "open collector" amplifier switching circuit such as in the Yaesu FT-857D and the FT-757GX, I have both transceiver and neither transceiver can safely switch the Heathkit SB-200/201 and SB-220/221 amplifiers!!! Most of these transceiver have "open collector" amplifier switching circuits that have a low DC voltage and current levels. The Yaesu FT-857D, for example, has an "open collector" amplifier switching circuit that has a maximum "positive" DC voltage of +50VDC with a

maximum switching current level of 400ma. Failure of the operator to read this warning can permanently damage those transceiver. Believe me, there have been those hams who thought it was not important to read the manual. Instead, they connected the circuits together and "poof", instant damage, all because they were too darn lazy and didn't think it was important to read the manual!!!!!

Most, if not all open collector switching circuits do NOT allow for any AC or "negative" DC switching voltages. I constantly emphasize to members the importance to spend time reading and studying the manuals for their ham gear. Quite often problems experienced could have been avoided if the member/operator would only pick up the manual and read it!!!

While the TS-520 and TS-820 have relay terminals that can handle the Heathkit SB-200/220 (SB-201/221 for amps that do not have 10 meters), it's best to use a relay interface between the amplifier's RELAY and the TS-520/820 rear panel relay terminals. Each time the relay energizes a spark occurs which result in carbon on the relay terminals. Over time the carbon build up can cause problems later on.

Now, having said all that and as I said before, you DO NOT need an amplifier interface when you use any of the Ameritron amplifiers, the AL-811 and AL-811H amplifier relay voltage and current levels are very low and easily handled by the KW hybrid transceivers, including the T599 and TS-510/511 earlier transmitters/transceivers. But there again, I can't emphasize the importance of spending some time with the Cell phone/ipod turned OFF and reading/studying the ham gear's operator's manual!!!

One more thing. You may hear hams say or tell you that you do not need the ALC connection between the amplifier and transceiver. That's a load of crap!!! You should always connect the amplifier ALC and transceiver ALC connection together. Simply follow the amplifier's ALC adjustment and you can't go wrong!!!

Mike,

There are some amps out there today that do not ever offer ALC connections, including the ACOM line - at least with their tube amps. Although I use ALC with either my 520S or 830S with the Heathkit SB-200 and Ameritron AL-80B respectively, I don't use, or better yet, _can't use_ an ALC connection between my 990S and the ACOM 1010 amp. The ACOM amp is driven to full output with only 30 to 40W of drive from the 990. The 990 doesn't have any ALC overshoot regardless of power setting, as I've checked it with my Tektronix scope.

My response was for amplifiers that do have the ALC connection. Naturally if an amplifier does not have an ALC connection then connecting the transmitter/transceiver's ALC to the amplifier is not required.

Where before it was not functioning at all (all digits "scrambled") on 15 and 10 meters, it now works 95% of the time on both bands. Once in awhile it's unhappy & reverts to it's scrambled version, but then corrects itself after a minute or so. So cleaning helped quite a bit, but not 100% yet.

Jeff,
Your problem is almost the same as to what I was having with my 820S DG-1 display. Cleaning the pins..etc...solved that problem for about 1 week or so..then it was back to being wacky. It seems that when it got warmed up..one or more through-holes would become unconnected with the other side. I pulled the DG-1 unit again the did the 'through-hole re-work." This involves having a bunch of short pieces of good wire..usually clipped off resistors..or other parts..and heating up the through-holes and inserting the small piece of wire. There are 18 such holes. Kenwood put out a service bulletin regarding the repair.It's a pain in the rear...and take about 45-60 minutes for the round trip.

I had to smile at Jeffs 1st report and chose not to rain on his parade. Never want to discourage new person who thinks they have found the cure. That is kind of person who is likely to succeed.

Have you verified that TC-1 has been properly set to provide close to 50mv of carrier to the CCR terminal on the Counter Mixer board? You can quickly check it at TP-6 on the IF board. I also like to check it at the molex connector at Counter Mixer Board (bottom side of rig).

The Service Manual Step 3.2 says to set the CCR level (Counter Carrier) to 0.1v (100mv) and that in my experience is way to high especially on the higher bands.

Lastly I have found that after doing the Vias on the Display board and reflowing some other connections on the Counter Mixer board and you still have this intermittent problem that you take a hard look at the two sets of "Intra-Board" molex connectors. If you look you will see that contact pressure is only applied on one side of the flat faced post. I would apply Deoxit D5 with artist brush to both sets of posts and then reseat the boards and sometimes this helps and other times not.

I run the unit removed from the radio with the covers off (I have a spare VFD display tube) and I gently touch each post with sharp end of soldering aid and if a digit blinks, goes out, or fades in intensity then likely that the contact being touched is not good. I touch each of the 17 "intra-board" pins in this way while watching the display.

I remove the two boards and I lightly sand all the Intra-board molex pins on the flat faces where the contact is being made. I then place a drop of full strength Deoxit DL-100 on each post and re-seat the boards. I have had very good success with this approach. If for example you have intermittent on 7mhz then likely problem is on T4 post.

Part of the problem that fools you is you can wiggle the molex connector on bottom side of chassis and cause display to come and go, you can pull/push on an individual lead wire entering that connector body, you can press/pull the circuit board, you can apply pressure to the shield can and all of these things can cause erratic display. Often you think you have narrowed it down to a connection and you really have not as the motion you apply at that spot is really just being transmitted remotely to the real problem area.

I charge an additional $40 for DG-1 repair and often it requires 3 or 4 pulls. Other big issue with the TS-820 is build quality and bad crimps on lead wires. I often find a board that has a long molex connector mounted and the connector body was not completely seated before soldering making pins at one end not fully protruding thru the board for soldering.

Lastly very common for an intermittent to be caused by a bad crimp on lead wire terminal or the spring metal end of that terminal is broken off and still laying down inside the connector body, but of course applying no contact pressure to its mating pin. This is a real fooler as you will read voltage when you apply a pin into the hole and touch the crimp terminal but there is no voltage going to the mating terminal post and associated PC trace.

These issues are why so many KW techs (and I mean some good ones) no longer service the TS820. I am re-evaluating my practice as I have been over run with T820s lately (5 here now and 2 on the way) and far too many hours troubleshooting intermittents. I am either going to have to raise price or do like others and no longer service. I no longer offer any warranty on a "fixed" DG-1.
I anxiously await the Arduino replacement and will gladly buy and direct my customers to make the exchange.

Each Hybrid model comes with its own set of unique design and as built issues that are now manifesting themselves more and more at the end of economic operational life. A TS-820 is a really nice radio (quiet single conversion scheme) when it is working and a real pain when it is not. Of course exacerbated by the very poor documentation.

Have fun

Terry K9TW

50190. RE: [TS-520_820_530_830] TS-820S display

From: David Boothe
Topic: 50165 Message: 50190

Good stuff, Terry. You and I have corresponded on my adventures with the DG-1 and I have appreciated your guidance very much.

Jeff, when I started seeing the issues on 21 and 28 mHz bands (really couldn't get a sensible reading at all), I did the following:

"For the high band display problem, I decided to check and set the Counter input level like it says on page 49 of the Alignment Manual (adjust TC1 on the IF board for 0.1 V at TP-6, then adjust T1 and T2 on the Counter Mix board to maximize the voltage at TP2). I adjusted this as close to 0.2 as I could (0.196V)."
Terry mentioned the first step in his note. I found the second step got the 21 and 28 mHz display back nearly all of the time. I also found that the 5V supply to the DG-1 was only running 4.7 V instead of 5.1 at the supply. After reviewing the circuit diagram carefully, I could see that the only thing between the two units was a wire (with Molex connectors!). Some cleaning got the voltage up to 4.9V at the internal DG-1 5V contact.
I have also resoldered all the vias, but I did not wire them. Cleaned all the contacts on the top and bottom Molex connectors and the 'intra-board' connectors, but all this has still not put me 'over the top' with complete 100% operation.
This unit had been a real pain and I've spent hours on it, but will likely do some of the other things Terry mentions around the connectors next time I have the lid off, especially the 'pin-by-pin' test. Hang in there! It's a great radio, but this is the one consistent issue with many of them.
One for Terry: what do you mean by the 0.1 counter carrier voltage being 'way too high?' What is the impact of having this on the high side? That's where I set it. Could this contribute to the issue? Thanks!

50191. Disarming a TS-520 DC Power Pack

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-20 17:05:06 UTC
From: roberteleazer@...
Topic: 50191 Message: 50191

In my investigations with the TS-520 I am working on, I have realized that if I was going to just power up the LV DC circuits I had better first deactivate the DC converter lest I get some HV DC showing up when I least expect it.

Anyone know how the simplest way to do that? I figured I will disconnect one of the leads from the large DC power pack terminal block.

Thanks,

Robert

Robert,

I don't quite understand what you are asking.

There are various lower DC voltages in the 520 such as the -6VDC +9VDC, +12VDC, +14VDC, -C (-101VDC), +210A, and the +300A.

Then there's the +920VDC for the plates of the 6146.

What Low Voltage (LV) and High Voltage (HV) are you referring to that you want and don't want?

Mike:

I am in the process of rebuilding the power supply section of a TS-520 that suffered a failure there. I have replaced the main power supply board (which was smoking on power up) with one that w s rebuilt and I'm in the process of recapping. The transformer looks pretty good in terms of the voltages it produces (not connected to the rest of the set yet) and the appearance and smell of it. I have yet to find a definitely bad cap among the ones I have removed, in terms of being clearly shorted, although some have a rather rapid decay time when charged up and then measured over time.

Before I am done with the power supply effort I would like to apply 14VDC in the manner that the original power supply did but using an external bench-type power supply and see how well the solid state portions of the set work. If too much is shot in that area then it's time to give up and use the set for parts. But if I just apply the 14VDC that will fire up the DC converter and bring the HV up as well, and obviously I don't want to do that yet.

I looked at the set and the power supply portion of the schematic this morning and have not yet figured out which wire to disconnect to prevent the DC converter from cranking up. I was hampered when the test lead on my VOM broke and I had to fix that first. I plan to just apply 14 VDC through the appropriate pins on power plug, since that is the first junction point for the 14 VDC output of the power supply board anyway.

By the way, are you still collecting power supply boards? I should be able to send you the old board from this one once I am sure I will not need it.

Thanks!

Robert

From: Mike W5RKL
Topic: 50191 Message: 50194

Robert,

The Rectifier Unit's "+14VDC" supply output is at the Rectifier Unit's "14" and "GND" terminals. The Rectifier Unit's +14VDC output is connected to pin 8 in the main power plug then through an internal jumper in the plug, connects to pin 9. Just follow the 520 wiring diagram and you'll see how the wiring is connected.

Now if you want to power the 520 with the +14VDC supply, all you have to do is disconnect the AC800, 300, 210, 100, and GND power transformer wires to the Rectifier Unit. Also disconnect power transformer "0" terminal which is part of the 300, 210,and 100 secondary windings, that connects to the junction of HV capacitors C31 and C32 (tape this wire so it doesn't short to the chassis). This leaves the 14VDC supply in tack and you can power the 520 14VDC circuits with main power. I don't know why you want to do this but that is how the 520 can be powered with Rectifier Unit's +14VDC ONLY. This will also give you meter and VFO dial lamps, driver and both final tube filaments lit if the Heater switch is set to ON.

If you have rebuilt the Rectifier Unit with new components then you should be checking the dual capacitor cans, C27A/B and C28A/B as well as the HV filter capacitors to ensure they are not shorted to ground.

Also, if you are checking capacitors with an ohm meter, the low voltage from the Ohm meter may not be enough to show the shorted electrolytic capacitor. If the capacitor discharges rather quickly when disconnected from any circuit then I would not waste time messing with it but rather replace it.

I'm not collecting boards but if the board needs fixing then I'll do what I can to rebuild the board providing the foil runs are not destroyed. My address is good on qth.com call sign look up.

Fellows what am I missing here??

If you just want to see if the Receiver works before investing any time and money in restoring the rest of the supply voltages why wouldnt you simply apply your 14vdc bench supply to the 14 terminal post and GRD terminals on the HV rectifier board or chassis ground? As I recall it will be a Blue wire on wire wrap post.

There is no need to lift anything. Your bench supply wont back feed thru the bridge rectifier or any place else.

You will simply be powering the 14vdc CLC filter and the AVR board and receiver will come alive. Of course you need the power cord plugged in but rig doesnt have to be turned on and certainly wont be powering the DC to DC converter and supplying any AC to the transformer primary windings.

OR

you could simply apply the 14vdc bench supply to the AVR board 14 wire wrap post (Orange wire) as you dont need the CLC filtering. If you do that dont need the Cinch Jones line cord plugged in at all.

Maybe I dont understand what you want to do?

By the way will need approx 3amp DC supply.

Terry K9TW

Hi Terry,

It appears that Bob wanted to power the 520 low voltage stages from +14VDC. It appears he was rebuilding the Rectifier Unit and wires between the power transformer and Rectifier Unit had been disconnected. I simply stated what wires could be disconnected between the power transformer and the Rectifier Unit preventing the 210/300 and HV from being present and how he could power the 520 low voltage stages using the 520's Rectifier Unit's +14VDC supply. If I misunderstood what Bob wanted or had done then I stand corrected.

David:

I use to set TC-1 for 100mv CCR level and with experience I have learned not a good level for stable display especially on 10 meters. You may even find this in print in some of the KW mods and "Service Bulletins".

I now firmly believe that setting CCR level to 0.10 volts (100mv rms) with TC-1 as called out in the Service Manual is wrong. It is too high a level as it overdrives the LO input to IC1 and Carrier Suppression goes to pot. 50mv is sufficient signal level to produce required LO input level at IC1. (suggest you pull up the data sheet and app notes for IC1 and look at the specs for the LO signal level).

The reason it is wrong is that it is on the border line of exceeding 200mv output at TP-2 assuming that you have adjusted the top coupled 7.830mhz LC Resonator Band Pass Filter properly. Important to adjust T1 and T2 for maximum RF voltage at TP-2 and not to set the level at TP-2 with them. Must set both LC networks to resonance ie peak rf voltage. At the Drain of Q2 Mixer you will have 1mhz, 8.830mhz, 9.830mhz and the difference frequency of 7.830mhz. This resonator circuit is designed to discriminate against all but the 7.830mhz signal. 7.830mhz is the Fc for this bandpass filter.

If you set TC-1 on the IF board to a level that exceeds 200mv at TP-2 you will be overdriving the SN76514N Mixer. The 7.830mhz signal at TP-2 is the LO (local oscillator) for this chip. If you look at the Data Sheets and App notes for this balanced mixer chip you will see that the LO signal level max spec is from 250 to 300mv P-P at Pin 5. 300mv P-P is 212 mv rms. The display may start to be unstable slightly below 200mv.

I find a good 7.830mhz level at TP-2 is approx 100 to 120mv or about half of 200mv. You obtain that by setting TC-1 for 50mv CCR signal level at the DG-1 and by peaking the RF voltage by adjusting T1 and T2.

You say you cannot get more than 196mv at TP-2 and that is strange as it should be very easy to obtain a level greater than 200mv assuming that you have approx 300mv of Carrier to the IF board at TP-5. After adjusting T1 and T2 to resonance (7.830) go ahead and adjust TC-1 on the IF board as you monitor TP-2 and you should very easily be able to attain as much as 290mv to 300mv. If you cannot then something is wrong and I would start by looking at CA2 level.

First set TC-1 for 50mv rms level at CCR molex pin on DG-1 and then adjust T1 and T2 for maximum level at TP-2. It should be around 115mv or so. It will depend in what test gear you are using. I use a Boonton 92E with no jumper leads at the probe tip or a DS1102 scope with 10X probe and no jumper leads from scope probe hook to the TPs. Scope tends to read a little higher than the Boonton.

I would do my measuring and adjusting at 28.5 bandswitch position and VFO at 250.

I am not correcting anyone. Just offering very simple solution if all he want to do is validate whether the receiver is working and doesnt want to apply 120vac to primary of the xfmr.

I am trying to understand his concern about powering up the transformer primary via the DC to DC converter and thus the xfmr hv secondary.

As you know the most common way he can get HV supplies energized via 14vdc is to install the optional Cinch Jones with the mobile operation jumpers in it and no reason to do that if all you want to do is just test the receiver. In 10 seconds can apply 14vdc to the HV rect board or as I mentioned go the AVR board. No Cinch Jones of any kind need be connected. Apparently this is not what he is trying to do.

If he wants to see if he can power receiver from the Cinch Jones with the mobile jumpers installed then yes he would have to defeat the DC to DC converter or lift primary or secondaries off the xfmr.

Maybe someday I will write something up on how the Counter Mixer Board works and provide Scope waveforms at all the TPs. I have them stored. When I get time I will transfer from my scope and put them on a flash drive and send to Joe.

I havent done that because about 90% of the time the issue is bad solder connections on the Display board or high resistance contact at molex pins. For the other 10% where the issue is a signal level or dc voltage or a component failure most folks dont have test gear to be able to troubleshoot it.

I have all this info but just very busy and shouldnt even be messing around here. I take a look in early am and from time to time during day. Old habits die hard.

As to the 830 Display I havent found the same poor soldering malaise as the 820, but others on here report that they have so better to just post and describe your symptoms and let those folks respond as to how they fixed it.

Dave

There are numerous errors in the TS-820S Service Manual. Very well known and discussed on this forum at length. Starts with the Carrier Oscillators being set to 50mv level vs 300mv level and is throughout the documentation (300mv is correct and not 50 or 500). Very common to find wrong signal level, wrong test point, and wrong adjustment devices called out. Have to look at each step very carefully to see if it makes sense before you proceed. Dont do any balanced mod or product detector carrier null by adjusting the called out trimmer pot or trimmer cap until you study the schematic or come here and ask if still not sure.

Teryy:

Thank you and Mike for your inputs. I do not want to apply power to the HV rectifier board because it is not all hooked up yet - at least not in away I trust. Applying DC at the AVR board is indeed a useful idea.

Tracing the circuits on the schematic and by use of a VOM on the set was laborious and somewhat productive. But the TS-520 Operator's manual provides what I need.

The table at the top of Page 16 shows how to wire the AC and DC power input plugs. Pin 9 of the connector is listed as "13.8 VDC to operate the solid state circuits."

Pin 9 normally would be jumpered together on the DC power input Plug with pins 2, 4, 7, 11, 12. Pins 11 and 12 are for the DC Power Module input power and so I won't need those. Pin 4 provides for control of the DC Power Module so I won't need that. Pin 7 is for the tube filaments and I won't need that either. Pin 2 is to run the power through the main power switch, so i will not need that.

So, it appears that, assuming the power input plug I use does not have those all pins jumpered together, I can apply power just to pin 9 and that should do it. That connection alone, along with a ground connection to my bench power supply, of course, should be adequate.

I can easily wire up a dedicated power input plug for the test purposes. I have something like 21 of those plugs in my parts stocks and not installed on power cords so I can well afford to use one to make receiver test plug.

Thanks again!

Robert:

Dont you have the covers off the radio? Even just the top cover.

In matter of seconds you connect a mini grabber or alligator lead to the 14 vdc wire wrap terminal post on the AVR board and the receiver will come alive.

Applying 14vdc to the 14vdc wire wrap post on the HV rectifier board is not "powering" the board or back feeding the transformer in anyway. Unless of course you had a bad carbon track at the 14vdc bridge rectifiers or the terminal post which could place a short on your bench supply.

When you connect 14vdc to the 14vdc AVR post you will have 14 vdc back feed thru the C-L-C Pi filter back to the HV rectifier board. If worried about that simply lift the blue wire off its post on the HV rect board.

I dont understand the need to power thru the Cinch Jones plug on rear of rig?

Terry:

This is a set I bought on ebay that had a serious power supply problem. There is considerable smoke residue inside the covers. The former owner had cut all of the output wires coming from the rectifier board and stuck in patch wires (apparently using that color coded single conductor wire salvaged from those big telephone cables). I assume it was so he could isolate the different power supply outputs and thereby track down what was causing the apparent short.

Powering up the set produced copious smoke from the HV rectifier board. Since I had a repaired spare board handy I just replaced the smoking one and started the recapping. I am still working on the recapping - I built my own multisection electrolytic caps using pill bottles to replace those hidden under the marker board, and one of them has too fast a decay rate to suit me; it'll be a do over (apparently hot melt glue gun glue is not a particularly good HV insulator). I am assuming right now that the original short was the result of a bad cap, but I do not really know. At least two of the old ones had bad decay rates after I charged them up but none literally are smoking guns

Anyway, the HV rectifier board is not yet hooked up correctly all the way. There are bare connections all over the place, and I am still tracing wires to see how badly (or goodly) wired things are, given that I did not do the wiring in the first place. I found early on before the recapping began that someone thought it a good idea to hook up the HV AC directly to the big filter caps without the rectifier board in the middle, so I trust nothing about the set that I have not done myself!

Powering the solid state stuff off the power connector using my 0-20 VDC 50 amp bench power supply, which is easy to do, will enable me to see how much current the solid state stuff is drawing - not only the receiver but I hope those solid state parts that activate when you hit the transmit button as well. And I'll be able to see if the receiver is working at all - without involving that highly suspect wiring in any way.

I will check the AVR board for voltage after I get the LV B+ hooked up. Thanks for that idea!

Wish me luck.

As to the 830 Display I havent found the same poor soldering malaise as the 820, but others on here report that they have so better to just post and describe your symptoms and let those folks respond as to how they fixed it.

Terry K9TW

Both 830S's I have had/have display issues. The first one (a 2M SN) I learned from had at least 2 poor solder connections. The first one I found was that hang on electrolytic on the bottom of the board C28 that brought the display to life. Then the loss of the counter signal was a bad solder joint at C1, that tiny cap near connector 2 that couples the counter signal to the board. On that board, someone had already hacked it up & removed connectors 1 & 2, and directly soldered the leads to the board! What a mess. I found male/female connectors on Ebay with the right pin spacing (0.1") along with the pins for both & redid the 1 and 2 board connectors. I have more of these if someone needs some, but they are awful cheap and it may be easier to just order them on Ebay. I can provide links, just contact me off group.

The second 830S display (a 1M SN) is somewhat intermittent and it seems it is associated with connector 2. This unit was intended to be a donor unit as it was smashed, but looks pretty good now, but more work to do. - Bob W8RMV

50210. Connector Surpise

In case y'all have not found out yet, different manufacturers of the 12 pin power plug connectors number the terminals in different ways. Cinch Jones plugs are numbered one way, connectors of the same exact design made by another company (Molex, I think) are numbered differently. I had previously noted that fact, discovered while looking through parts catalogs, but today I got bitten by it myself.

I took one of the many female power plug connectors I have on hand and tried powering up just the solid state electronics in a TS-520 via Pin 9 of the power plug. The dial lights came on but that was all; I could not find power anywhere else in the set. I thought it odd they would not put the dial lights on the filament string but figured that the removal of the LV filter caps had broken the rest of the string.

Then I started looking at the schematic. Sure enough, the dial lights were on the string with the filaments. I realized that I must have hooked up the wrong pin, Pin 7 instead of Pin 9. How stupid!

However, examination revealed that no, I had indeed soldered the power lead to Pin 9. Then I looked at the back of the male connector on the chassis. Pin 9 connected to Pin 7 on the female socket and vice versa!

So keep an eye out for that problem. People occasionally contact this group and complain that they can't get their power plugs to work and typically are advised to just pay attention to which pins are used. But sometimes that won't work.

Have a good weekend!

Robert

This is why I tried to steer you away from this method of powering the rig. As I have mentioned very easy to power radio at 14vdc wire wrap post on the HV rectifier board or the AVR board and it will not back feed any of your lifted leads.

Far too easy to get turned around wiring this plug. It is not a "Cinch Jones" connector although most of us commonly call it that.

It is a Japanese connector (JCJ12F) and not a American (S312CCT) connector. It is essentially a mirrored image for the numbering scheme.

Go to the Yaesu site and download the Zip file that you will find there.

Topic: 50212 Message: 50212

Any DG-1 repairmen out there have a copy of the Xray view of the later issue Counter Mix Unit board (X54-1150-00)?

All the service manuals that I have searched have the J25-1391-03 board and the later production run TS820s use the J25-1391-13 board. It has changes that have been discussed here before such as a 10 mhz 2 transistor colpitts oscillator in place of the IC2 1mhz oscillator and the addition of VR-1 trim pot to IC1 balanced mixer.

As a point of interest I have had 3 boards this month that all had burned open 14vdc supply L21 470uhy choke and two with failed IC2 chips. These things are all getting long in the tooth.

Thanks
Terry K9TW

Hi David:

Yes that is why I posted here. I hope that a member that owns a late serial number TS820 purchased the late edition Service Manual and can help.

That assumes of course that KW revised the Service Manual to reflect the changes to the DG-1. They may not have done that.

As far as I know the latest Rev of the TS830S Service Manual is the 3rd Edition, but I cannot tell you what is the latest revision to the TS820S Service Manual.

Serial number convention, issuing of so called "service bulletins", issuing revised manuals and errata sheets was not a KW strong point. The conventions they use may be meaningful to them, but sure not very clear to customers on this side of the pond!

I am thankful that you pointed me to the correct schematic in the Owners Instruction manual. That has been very helpful for troubleshooting. Would just be nice to have the correct X-ray view. It would seem to me if they revised the schematic for the Owners manual that the board x-ray views would have been revised in the companion Service manual.

50216. Hybrid Net Update (November 23, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-23 23:48:33 UTC
From: Mark Gilger
Topic: 50216 Message: 50216

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There were 37 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)

4 running TS-530(x)

4 running TS-820(x)

9 running TS-830S

0 running TS-511

0 running 599 twins

I was running my Drake 'C' liine & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were 30 stations checking in under fair band conditions. He had the following number of radios checking in.

5 running TS-520(x)

0 running TS-530(x)

2 running TS-820(x)

6 running TS-830S

0 running TS-511

0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my Drake 'C' line & Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday□s net total 106, Sunday□s total = 68 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:

Bob,
As you know all KW hybrids have a 'slow motion vfo.' The gearing is rather cool if you look at how it operates. Unless someone has superior machining skills and re-worked it...which it doubt...the VFO is nothing special. Someone is obviously not familiar with the rig/vfo.

Wes..

This is a hybrid Kenwood group, not a forum for you to air your dislike of Microsoft software.

There is nothing to replace it, there is no software that is malware free. Ergo, we get to use it.

An FYI....If we users have an up to date anti-malware software installed, the occasional attempt to mine information, or to spam us, will not hurt us. Your anti-malware will pick it up and block it. There is no need to go into a hissy-fit every time someone's email addy get hijacked and used to send along spam.

Let's stick to the topic of Kenwood radios, without the 'the sky is falling' histrionics. Please.

Joe - W7RKN

Terry:

Yes, I thought about your recommendation when I was attempting to figure out why nothing but the dial lights were coming on. In fact I was looking into doing that via the AVR board but ran out of time.

I had hoped to make some progress yesterday but I had no sooner got to the airport (where I am working on the TS-520, so I could devote part of a workbench to it for an extended period) than a friend came up and said his organization was getting rid of a bunch of old military radios and did I want them? I looked at what he had and replied that yes, indeed, I wanted them. So I spent my available time looking at my new acquisitions and trying to figure out what they are. I expect to get back to the TS-520 today; at least the time spent studying the schematic will be useful during the recapping.

BUT - I am sure glad I found out about the mirror image numbering of those connectors the way I did. Since I have 20 of them and I am going to be building at least 4 power cords, I am glad I did not find out by running 120VAC through the 12VDC circuits.

Thanks again!

Robert

From: pmarkavage@...
Topic: 50212 Message: 50225

Let see if I can shed some light.
The original TS-820 operating manual, B50-1568-00, shows the IC-2 and no 2-stage oscillator.
This manual was never updated to a suffix -10, -20, etc.

The TS-820 (S) service manual, B51-0807-00, was somewhat in sync with this operating manual. As far as I can tell, this manual was updated four times, suffix -10, -20, -30. At no time did Kenwood address the circuit changes made on the Counter Board, X54-1160-00, even though later TS-820S models had a new board design (J25-1392-13). It also did not address other changes like new display tube information nor a different display unit board. I'm sure there were other anomalies.

The operating manual for the TS-820S, B50-2529-00, had the new circuit changes in the Counter Board addressed in the included schematic. Likewise, it also included the new display tube information (original display tube was discontinued). As far as I can tell, this operating manual was never updated beyond suffix -00.

There was never a noted "REVISED" or "ISSUE #" on the service manual as they did with the TS-830S/M manual. Issue 3 was the last iteration of the TS-830S/M manual.

There is a soft surge under the final area when I dip the plate current and I see a flash coming from under the tube sockets. This happened after I cleaned the bandswitch. The rig worked fine until I lost 40 and 80 meters. That's what prompted me to clean the switch. HV is good. No forward power at all.

Any idea's. Thanks.

Tom.

Tom,

I recommend you check the two 6146 10 ohm 1 watt cathode resistors and the two 6146 100 ohm 1/2 watt screen resistors. Normally but not always, the 6146 screen resistors do not fail but check them anyway.

Do you still have 60ma IP idling current with the MODE switch in LSB or USB, MIC gain set fully CCW, the meter switch set to IP, and the transmitter keyed with the microphone PTT button or the SEND switch ?? If the answer is "No" then check the cathode and screen resistors I stated above.

The cathode resistors are the 6146 "common current return path" for 6146 grid, screen, and plate currents. Open 6146 cathode resistors will open the grid, screen, and plate current return path resulting in loss of current flow in the 6146 tubes, hence no IP idling current indicated in transmit.

Failure of the 6146 screen resistors, each tube has one 100 ohm 1/2 watt screen resistor, can also result in the same indication, providing the cathode resistors are not burnt open. In most cases, but not all cases, the 6146 screen resistors do not fail.

Arcing in the base of the 6146 can indicate excessive gas in the 6146 tube(s). Arcing in the 6146 can, but not always, be an arc that occurs between the 6146 plate and beam forming element. The Beam Forming element inside the 6146 is connected back to the cathode inside the tube as well as at the tube socket pins 1, 4, and 6. If this type of arc occurs, the cathode voltage will rise to the level of the plate voltage, +900VDC. This results in approximately 180 amps of cathode current (900 / 5 = 180). The power dissipated in the cathode circuit is 162,000 watts (180 x 180 x 5 = 162,000), resulting in each cathode resistor dissipating approximately 81,000 watts (162000 / 2 = 81000) causing both cathode resistors to burn open.

Tom,

Have you checked the final amplifier cathode resistors, there are two 10 ohm 1 watt resistors? I suspect the two 10 ohm cathode resistors burnt open which is the "Pop" you heard.

Since you had the meter switch set to IP when this happened, the only path electrons had to take was through the IP meter circuit so the current flowing through the meter circuit went through the roof which caused the meter to peg hard to the right against the peg stop. I have a video on my website that shows what happens when the TS-520 cathode resistor burnt open.

www.w5rkl.com

Clock on the "Video" link at the top of the page and when the page comes up, scroll down to the TS-520/820 Final amplifier TUNE Cathode and IP meter circuits" links.

The final amplifier consist of two 6146 wired in parallel with two 10 ohm 1 watt cathode resistors hanging from pin 1 on each tube socket to ground (chassis). If these resistor look burnt then replace them. If you have an ohm meter, connect the ohm meter to pin 1 (RED probe) and common (BLACK probe) to the chassis. Set the resistance level to measure 20 ohms or a level close to that. If the cathode resistors are good, you should see "5 ohms" (both cathode resistors are wired in parallel. If the resistance is infinity or significantly higher or intermittent above 5 ohms then the cathode resistors need to be replaced!!!

Well we all unfortunately could share stories of how we learned the hard way. At least those who were fortunate enough to walk away with only pride and pocket book hurt.

I do appreciate and applaud your safety sensitivity. Anytime you place one of these radios in a non standard wiring config for testing purposes you have chance to get hurt or destroy something so what you propose to do has to be evaluated and never hurts to come here and ask for a head check just as you did.

Also lifting leads and installing jumpers isnt only act that can get you in trouble. Making assumptions and relying on wiring and color conventions can get you in lots of trouble. Defeating interlocks and blocking relays and relay contacts has to be well thought out. Have to recognize the risks and use appropriate risk management measures.

Thanks Pete I was afraid that was the case.

I have been helping an individual off the reflector and explaining why KW engineers added VR-1 IC1 Mixer Carrier Null pot and how to adjust it and what the effect on the display is if the 7.830mhz LO carrier is not adequately suppressed.

That individual asked good question as to why there wasnt any documentation and I couldnt say with 100% certainty that there wasnt a revised Service Manual out there. It seemed plausible to me that there would be given that KW had updated the Owners Instruction manual schematic.

I am able to do the work absent the Xray view of the board, but would be nice to have one.

Thanks
Terry K9TW

50233. TS-520 AVR Board Discovery

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-25 02:16:12 UTC
From: roberteleazer@...
Topic: 50233 Message: 50233

I finally succeeded in powering up my "in-work' TS-520 via 12 VDC applied to Pin 9 of the power connector.

I could hear a hiss coming out of the speaker, but it was not very loud, although its strength was affected by the main audio gain control.

I checked to see if I had the proper voltages on the AVR board and was surprised to find that touching one of the connections - the "posts" sticking up - caused the noise from the speaker to increase in volume and to include "radio static" type of noise.

In fact, if I pressed on that post with a screwdriver fairly hard, I could tune in a strong 25 KHZ calibration signal with the main tuning knob.

So it sure seems like that there is a cold solder joint or something like that at that post. Right now I do not know what that connection is for, but it is one of the larger ones on the middle of the side of the board, one that seems to be hooked to shielded wire.

I hope to work more on it tomorrow.

Thanks,

Robert

I am able to do the work absent the Xray view of the board, but would be nice to have one.
Thanks Terry K9TW "

When Kenwood updated any page in their operating manuals, the suffix "-" number was increased. The TS-820 operating manual was never incremented up in it's suffix "-" number nor was the TS-820S suffix "-" number. The schematic changed when they went from the TS-820 operating manual to the TS-820S operating manual but the manual part numbers were different (i.e. two different manuals).

I believe that it would go to full scale because the meter is in series with a 3K resistor that would be across the (now open) 10 ohm resistors so it would see a relatively high voltage. Fortunately, the meter seems to survived unscathed.

I appreciate the heads up there and I will take a look at the resistors ASAP, but I am really interested in finding out if the light bulb is still suitable for a test load or do I have to find a better dummy load. I could kick myself for getting rid of the Cantenna.

Showing my age, but I used a bulb on my first transmitter, a Heath DX-20 in 1959. But there are several problems: light bulbs do radiate somewhat. A cold bulb has different and changing resistance as it heats up. I'm sure there are other issues as well.
I think if you can purchase even the MFJ 100 watt or 300 watt dry dummy load (around $45 I think) much better in the short and long run, since I don't believe the bulb will provide the known non-radiating 50 ohm load you need to tune into if using an antenna tuner to match your antenna, or an amp.
I have seen Genuine and home brew "cantenna" for sale on several site like QTH, and..eBay. I had one too, but can started leaking after 20 years.

Well, I ran some more tests early this morning and the "cold solder joint" problem seems to have gone away. The problem was with the output lead but it is working Okay now.

I was bale to get a 25 KHZ calibrator signal on all bands, although it was much stronger on WWV. I have seen on my other TS-520 that the WWV switch tends to get sticky in the antenna area. So I cleaned all the switches on the front with electronic cleaner.

The rig does seem to be working, so it's on with the recapping and rebuilding the power supply!

Thanks, all!

Tom,

MFJ sells an dry 300 watt dummy load for $36.95 plus shipping. I use one on my bench but the maximum time a steady carrier can be applied to the 260C dummy load, at 100 watts, is 90 seconds, see the 260C manual for details.

http://www.mfjenterprises.com/Downloads/index.php?productid=MFJ-260C&filename=MFJ-260C.pdf&company=mfj

You are correct, the full anode current will flow through the simple series IP meter circuit if both cathode resistor burnt open.

The IP meter circuit actually measure DC voltage but displays the voltage on the meter's top scale as current.

The internal resistance of the TS-520 meter is approximately 600 ohms. This value can vary from meter to meter but not by much.

The 3.3K resistor you refer to is the meter multiplier resistor. You can determine what the voltage level that will be applied to the meter at any given IP current level by simply performing the Ohms Law math calculations shown in my video.

Topic: 50228 Message: 50239

What with the upcoming holiday, any troubleshooting will be delayed. I am curious, though. Assuming that the cathode resistors have let go (a very reasonable possibility which would certainly explain the condx) why would they? Old age? Bad bypasses allowing too much RF current to flow thru them? Did I do something wrong during tune-up?

The reason why I ask is that I knew that the output tubes could be a little...well...old...so I was being very judicious in the amount of plate current I loaded up to. Since the book said I could go up to 200 ma, I was keeping it at a very sedate 150 ma. That gave me about 50 watts and that was good enough.

Any explanations?

Tom, K3WFN

Yep, I figured that all out. The only reason I can see for the 10 ohm resistors is to provide a shunt to read the plate current. The 3K resistor + the meter's internal resistance set the scale for the meter.

I took your suggestion and sought out the cathode resistors. Sure enough, they're gone. Not completely open, as I might have expected based on the pop, but each with a resistance of about 3K. In fact, only one even looks like it even had a problem. It has an almost invisible crack on the bottom (unseen, naturally) side. The others look like they just came out of the drawer.

What is more interesting to me is that 1) you knew right away what to look for and 2) that they had already been replaced by the previous owner, so this must be a recurring problem with TS-520s, but I'm not sure I understand why.

The DC power dissipated in either of the 10 ohm resistors should only be about 0.1watt [i.e. 100 ma per tube = 0.1A thru each resistor. (0.1A * 0.1A) * 10 ohms = 0.1 w]. The two 1/2 watt, 22 ohm resistors that the previous owner put in parallel produced an equivalent 11 ohm (not perfect but close enough), 1 watter. If this is just a DC problem that combination should have lasted forever.

Could I be seeing excess RF currents due to bad/or open cathode bypasses? I don't see any other reason for a failure.

Hi Tom,

You can find new (NOS) 6146Bs at various on-line outlets,

1. https://www.tubedepot.com/products/6146b-8298a
2. http://www.rfparts.com/catalogsearch/result/?q=6146
3. http://www.vacuumtubes.net/Prices%206000%20to%207199.htm

If you replace the final tubes you will have to neutralize the final.

Yes Tom, you're very close. For example, if the cathode current is 225ma and each cathode resistor is 10 ohm 1 watt, each cathode resistor will dissipate approximately .127 watts (127mw), which is not even 1/4 watt.

.225 x 5 = 1.125(cathode voltage)

1.125 / 10 = .1125 (current flowing in each cathode resistor, it's NOT the same as the total cathode current!!)

.1125 x = x 10 = .1265 watts (the "x =" is the same as pressing the Square key after entering .1125 on a calculator keypad)

Even though the cathode power dissipation is low I would not lower the cathode resistors power rating to a level that's less than 1 watt.

If you suspect the 6146 tubes are toast then I would replace them. You initially said they seem to be old. Not knowing what the tubes have been subjected to over their life span, you can't say with any certainty what condition the tubes are in, especially after this failure. I have seen 6146 cathode resistors fail after being subjected to constant high current levels such as running RTTY at constant high output power level which should never be done, the final amplifier is not designed to operate at constant high RF output levels.

In most cases you do not have to replace the 6146 100 ohm 1/2W screen resistors.

I have a 520S that is pretty far gone(had to evict a mud-dauber nest), no real attempt to troubleshoot was made other than to note that the rectifier board was burnt into multiple pieces. I got it for the VFO, which I am using to repair my 820. VFO tested and working, so not everything was killed by whatever got the rectifier.

Anybody want parts? Since I am not fully equipped to test this stuff, I'll be sending most of it just for the cost of shipping... I already got my money out of the VFO. I have basic test equipment, and can take good pics of any part you want.

Thanks for the help Mike.

I recently repaired this rig due to a foolish mistake on my part. I mis-read the line fuse and fried diodes and resistors. The rig sat for 3 years with a bad fuse. Don't remember what happened. I replaced cracked diodes 8,9,10 and 11 on the rectifier board along with new filter cap's. Resistor's 1,2,3, and 6 on the same board. I'm getting 912v off the 800v out pin on the rectifier board I wondering about that as a suspect.

I did replace the 2 cathode resistor's as well as the grid screen resistors. After that the rig ran good for 2 weeks made plenty of contacts. Then I lost 80 and 40 meters so I suspected the bandswitch and cleaned it. Then this happened. I checked all the components I installed and they are good. Idling current is 60ma. HV is good as well as ALC.

No forward power on swr. I sure the tube are bad now. I have a spare set but have to fix this before I use them. I studied the schematic over and over again and at a stand still. That's where I'm at now.

Tom,

Seeing 912VDC at the Rectifier Unit's 800 terminal is not unusual. The KW hybrid's all have a voltage doubling HV power supply. The "AC800" winding on the power transformer secondary is NOT 800VAC but rather an AC voltage that is significantly less.

The 2 HV filter capacitors, C31 and C32 both 100ufd at 500VDC, are wired in "series" resulting in a total capacitance of 50ufd (100 x 100 / 100 + 100 = 50). Capacitors in series are calculated using the same formulas that resistors in parallel use. Since both capacitors have the same value, 100ufd at 500VDC, you can simply divide 100 by 2 and get 50ufd total capacitance but the combined maximum operating DC voltage "doubles" to 1KV. Each capacitor charges separatelybut the capacitors discharge together as one 50ufd capacitor.

The Rectifier Unit's "HV Unit 800" terminal accepts the 912VDC from the Rectifier Unit's "800" terminal and through the series resistor voltage divider consisting of R1, R2, R3, and R4, drops the 912VDC down to a voltage level at the junction of R1 and R2, that is applied to the HV Unit's "HV" terminal and ultimately through the meter switch HV position to display the final amplifier's HV. If you measured the HV Unit's "HV" terminal, it would be very low.

By the way, the meter switch positions are "disabled" in receive. The meter displays variations in the receiver's AGC voltage, i.e., displays "S Units" in receive. This is accomplished by relay RL2-2 as seen on the 520 schematic.

Nathan:

Well, that is a generous offer! While I am repairing a TS-520, I don't think I'll need anything else. It is missing the cover over the final amp section but I should have no problem fabricating a replacement out of scrap aircraft aluminum plate. It's also missing some knobs but I have already replaced them with non-Kenwood knobs (Radio Shack) and I'm satisfied with that.

I recommend that you consider selling the transformer if it seems to be Okay. Those tend to be pricey items and are not too common. Or - you really might want to retain it for your TS-820 as a spare, since it should work there as well; that is what I would do.

Best Regards,

Robert

Robert,

Why would you install a collection of four 68ufd electrolytic capacitors to replace the two 100ufd 500VDC caps when Ken, K4EAA, sells 120ufd 500VDC replacement caps for $24.99???

http://www.k4eaa.com/parts.htm

Scroll down the page and you'll see the HV cap replacement kit he is selling.

Now lets look at the cap configuration you are considering. You say you have four 68ufd caps that you plan on wiring in "series/parallel". You did not say what the voltage rating of each cap is but I'll assume it's at least 450VDC for each capacitor. Hopefully I'm not making a bad assumption here!!!

Now, connect 2 of the 68ufd caps in series, what is the total capacitance and total working voltage? The answer is 34ufd at 900VDC (68 x 68 / 68 + 68 = 34) and the voltage rating "adds" so the series string voltage rating is now "900VDC". Repeat this with the other two 68ufd 450VDC caps and you get the same results. Now you have 2 series string caps with a total capacitance of 34ufd at 900VDC "each string". When you connect the 2 series string caps in "parallel" the total capacitance is now 68ufd but the working voltage is still at "900VDC", not "1800VDC" as one might think!!!

As for an increase in HV the answer is no. If you are asking will the working voltage of the four 68ufd 450VDC series/parallel capacitor connections result in a working voltage of 1800VDC the answer is "No".

Personally, Robert, I would not do what you are considering doing. I would spend the $24.95 and purchase Ken's HV cap replacement kit and be done with it!!

Topic: 50228 Message: 50259

Tom,
I may get flack for this, but there is an alternative to the $50+ per tube prices for 6146B. My “project” 820S had low output and its GE JAN 6146Ws were shot. I ordered NOS 6146B’s from the Tube Center in FL, but they sent me Chinese tubes ($20 apiece). They offered to exchange them, but I needed finals and tried them out. I idled them in the rig for 3-4 hours before (carefully) neutralizing and tuning into a dummy load. They have worked exceptionally well in the rig over many contacts in the past couple months—solid 100W at 225ma plate current on all bands with good, sharp plate current dips (including 10M). I had also installed a new driver 12BY7A (obtained from K4EAA) and that helps too.

Maybe I’m just lucky—you see quite a few stories about flash-overs, etc, but I’m satisfied so far. The only labeling on the tubes is “CHINA 6146B.” I’ve also seen plenty of stories about flash-overs and defects with NOS tubes, too, so I’m just saying there is another option as the other supplies dwindle. High-potting any new candidates would be good, if you have the equipment (I do not).

Greetings Group,
RE: Ken Kemski-k4eaa
So as not to violate HIPPA..the all inclusive medical privacy LAW,
Ken has had some difficulties in the recent past, and maybe experiencing them again. He also gets swamped with "help me emails."

His wonderful XYL- Barb takes care of the orders that come in and gets them processed really fast.
So, that's all I can say about that.

Mike and others:

Any tips on would take to build a “flashover tester” for 6146B tubes? I’m thinking that such a device would provide 800 VDC, with current limited to 225 ma, to the plate and if the tube didn’t flashover, there is at least some assurance (not 100%, of course) that the tube won’t flashover when installed in an HF rig.

What other elements of the tube would need power to do a basic flashover test?

(Appropriate safety precautions would have to be built into the device, of course.)

Louis,
What a coincident, I'm working on a "tester" right now. I have thought about this, and I feel an old hybrid transformer is enough to provide all the power needed (I do use a small filament transformer on a variac). I salvaged a transformer from a junked 820 (strapped to 120v) and I have been experimenting with it and I did some conduction tests on all my 6146 tubes so far.
I'm using voltages directly off the windings up to this point. Highest plate voltage so far is about 300v, bring it up on a variac.
I power the screen too, but its not as high as the plate, and you don't want it as high (a 10:1 ratio in voltage is about right). I also have a 2W resistor in series in the secondary winding to limit current in the secondary winding. I'll need to get a larger glitch resistor in there, when I go for higher plate voltage
My next step is to raise the plate voltage, so I can achieve a flash over. When I have a good design for the 6146s, I'll build a larger one for power amplifier tubes to include the 3-500z and the external anode ceramics.

(I also have built a 10kv (100uA limited) hipot tester, and have run some leakage tests on my 6146 tubes. I now hipot all my new tank components (like C1 & C2 in a Pi-circuit) and if they arc over, I can work in that arc area and file down the sharp edges and/or apply corona paint to those areas. That assures I have some good components to install in my homebrewed amps)

Like Mark, I can attest to the efficiency of Terry's mod. I installed it in each of my hybrids, one of which suffered a "new" tube flashover event with no harm to the radio whatsoever. I am happy to be relieved of the annoying cathode resistor changing task while using the rig itself as a "tube tester."

Well, its like this:
300v at 200mA plate current; R = 1500 ohms to start with.
Also, as a reminder don't float the screen & grid. I apply voltages to
G1 & G2. Need a resistor in series with the screen.
So far, I use the screen taps on the transformer. I make a voltage
divider on the filament taps (0-12.6) to get the 6.3vac, then I pick off
and connect the grid with 6.3vac. The leads needs to be swapped around
to find the most plate current.

Jan:

It doesnt sound to me like you are making a "flash over tester"???

You are making a dynamic load DC tube tester. No different than running the tubes in an old DX-100 or similar transmitter (other than slightly higher plate voltage) with no RF drive prior to installing in your KW hybrid. I am not sure what you are trying to do. I use to run my spares and new purchase 6146 tubes in an old DX-60, but it didnt have same anode voltage so wasnt exactly mirroring same operating conditions as the hybrids. I planned to increase the anode voltage and never got around to it and I realized without rf drive and same rf voltage swing I wasnt really doing anything. Dont want to get into the "cooking or gettering" debate that has been beat to death here. If you want to "cook" it cant hurt that is all I will say.

I soon realized I needed a DC hi-pot and as you note very good for testing air variables and other components. I became familiar with Hi-potting thru my electric power utility career.

Some fellas build these dynamic dc tube testers and install full metering (Plate, Control Grid, Screen Grid) and variable bias voltage,screen grid, and anode voltage so they can run family of curves. Typically they use these test sets for high voltage high power linear tubes so they can subject the tubes to dc operating conditions in something other than their several thousand dollar linear amplifier which they dont want to subject to possible damage from fault currents.

You already have a 6146 "flashover tester". That is the DC hi-pot.

The 6146 tubes in our radios see approx 1600 rf volts peak to peak in service. Assuming 850vdc key down then 850 x .9 x .707 = 541 rms rf volts or 541 x 2.828 = 1530 P-P rf volts swing. So you should DC hi-pot the 6146 finals to a minimum of approx 2kvdc. You do that with a stepped voltage test. In my experience a good 6146 will hold off 2500vdc with no ua leakage current at all.

If the 6146 tube should arc over during hi-potting (anode to beam plates ie cathode) the tube will not be damaged as you are limiting the energy by limiting the current to 50ua to 100ua. Power = E x I so 2500 vdc X 100ua = 0.25 watts. Sometimes after tube breaks down during hi-potting it may not have any leakage current on the 2nd run up. If it does have any leakage on the 2nd run up I dont use them in my rigs and recommend that customers do not.

If you build a "flash over" tester that applies 900vdc to the 6146s you may find some that will arc over and some that will not at that anode voltage. That does not mean that those that did not wont do so in the KW Hybrid with RF drive.

Have fun.

I forgot to mention it sounds more like you are building a fault current burner and not a flash over tester.

Kind of a low voltage high current dc hi-pot. The whole idea of testing is to limit the fault current to a safe limit. How will you determine what that level is? Anything above low ua level may cause damage. What value of glitch resistor would you employ? How much fault current can the 6146 tube take without damaging it? Where would you find that information?

What limits the current in the hybrids today (other than correct amperage fast clearing fuse)? It is the 5 ohms of cathode meter shunt resistance and the ESR of the HV power supply. I dont know what the ESR value is but if you say it is 10 ohms then you are only limiting the fault current to approx I = 900/15 or 60 amps. 60 amps is a heck of a lot of current. Again what level of current do you think you can limit it to so the tube is not destroyed by your low voltage high energy test set?

In my protection mod I employ a 10 ohm glitch resistor and I hope that it along with 5 ohms cathode resistors and 10 ohms of transformer Equivalent Series Resistance will give me approx 25 ohms of current limiting. 900/25 = 36 amps. Still a lot of current, but significantly lower than just 5 ohms or 900/5 = 180 amps. 5 ohms of course is not correct as it ignores the transformer ESR.

Again I submit that the DC hi-pot is your "flash over " tester. This test set you are building now if not designed properly will be just a low voltage high current destructive tester. Electrical apparatus repair shops call them fault burners. Used in motor and transformer repair shops to identify the bad winding by revealing where the smoke emits from!

Maybe I dont understand what you are trying to do? That happens to me a lot!

Happy Turkey Day

Terry,
Okay, thanks for the info, its very interesting. This is exactly what I really love about the hobby; The thrill of discovery!
I need to study the terminology more so we can discuss this intelligently. I don't know what the phrase _"__dynamic load DC tube tester" _means. Is this how the TV tube testers work? I don't know. I wish I own an old TV tube tester here so I can look at it & understand the theory on how they work.
First off, I'm using AC directly off the transformer and I am hopefully not wanting to do high current testing, so that's why I added a few resistors.
Okay, let me read up on this "dynamic load DC tube tester" stuff. (WOW, sounds cool)
Best Regards & Happy Thanksgiving,

Terry,

Based on what you wrote, it sounds like the following steps would be a reasonable procedure to "out" bad tubes that might blow the cathode resistors before installing them in a rig:

1. Connect the DC Hi-Pot tester between the plate and the anode.

2. Set the tester current to 100 uA.

3. Gradually raise the voltage and hold it at 2000 VDC for several seconds. (/How long is enough?/? /How long is too long?/).

4. If the tube doesn't flash, it's probably safe to install the tube in a rig. End of Hi-Pot test.

5. If the flashes, shut off the tester, wait a few seconds, turn the tester back on, then repeat steps 3 to 4.

6. If the tube flashes again, put it in the scrap heap.

Is the above procedure reasonable? Is there any need to supply power to any other elements in the tube during the test?

  Like Mark, I can attest to the efficiency of Terry's mod. I installed it in each of my hybrids, one of which suffered a "new" tube flashover event with no harm to the radio whatsoever. I am happy to be relieved of the annoying cathode resistor changing task while using the rig itself as a "tube tester."73,Craig

I forgot to mention it sounds more like you are building a fault current burner and not a flash over tester.

Kind of a low voltage high current dc hi-pot. The whole idea of testing is to limit the fault current to a safe limit. How will you determine what that level is? Anything above low ua level may cause damage. What value of glitch resistor would you employ? How much fault current can the 6146 tube take without damaging it? Where would you find that information?

What limits the current in the hybrids today (other than correct amperage fast clearing fuse)? It is the 5 ohms of cathode meter shunt resistance and the ESR of the HV power supply. I dont know what the ESR value is but if you say it is 10 ohms then you are only limiting the fault current to approx I = 900/15 or 60 amps. 60 amps is a heck of a lot of current. Again what level of current do you think you can limit it to so the tube is not destroyed by your low voltage high energy test set?

In my protection mod I employ a 10 ohm glitch resistor and I hope that it along with 5 ohms cathode resistors and 10 ohms of transformer Equivalent Series Resistance will give me approx 25 ohms of current limiting. 900/25 = 36 amps. Still a lot of current, but significantly lower than just 5 ohms or 900/5 = 180 amps. 5 ohms of course is not correct as it ignores the transformer ESR.

Again I submit that the DC hi-pot is your "flash over " tester. This test set you are building now if not designed properly will be just a low voltage high current destructive tester. Electrical apparatus repair shops call them fault burners. Used in motor and transformer repair shops to identify the bad winding by revealing where the smoke emits from!

Maybe I dont understand what you are trying to do? That happens to me a lot!

Happy Turkey Day

Terry K9TW

Jan:

There is an AC tester in the files section for a 6146 tube. It essentially configures the 6146 tube as a Diode. Causes pulsating dc at the anode and is measured on a ma meter. It test the tube at much higher current than a conventional mutual conductance tube tester would do. More of an emission tester.

I agee that DC-hipot test tells you nothing about the tubes cathode emission. Can only find that out by placing in service or with a tester like in the files or such as you are building.

I thought primary concern was to screen out tubes that would arc over due to either 900vdc on the anode or 1600 volts rf swing. This is where damage occurs beginning with popping your cathode meter shunt resistors not to mention the stress on the HV caps, rectifiers, and power transformer dumping all that energy in microseconds.

I agee that a "dynamic load" tester would be nice and that is why I use to run my 6146 tubes in my old DX-60. Didnt care if I hurt it. I never found very many that were down on emission. Some folks would toss them if couldnt get 100 watts out and others run with 80 watts or so for many years.

I probably dont understand your objective and therefore should not have questioned what you are doing.

When I saw "flash over" tester being mentioned I immediately went to DC hi-pot as that is its function.

Hi Dave:

No I am using two series connected Ohmite Type OY. Either 4.7 ohm or 5.6 ohm is fine. Could probably go a little higher without causing too much IR drop. I just didnt have any values higher and you can see by the math what just adding 10 ohms in the path in series with the 5 ohm cathode resistor and the transformer ESR does to the fault current.

You do need to use surge or pulse rated resistors. I would not use a sand power resistor. Really no reason to use a series string of resistors at our anode voltage. That is done for higher voltages (3kv to 4kv for example) so dont track over just one current limiting resistor. Reason I am using two is I couldnt find a single 10 ohm pulse rated resistor. I dont think Ohmite makes them in OY design?

Of course two schools of thought about surge resistors in amplifier plate supplies. Some want the surge resistor to be sacrificial and explode (they incase them to retain the shards). I dont want that on a Tetrode. Never want anode supply to open while SG is energized. A good way to exceed its dissipation and destroy the tube (As Mike and I have mentioned here in the past).

Same for all Hybrids.

Basically same anode supply and same cathode circuit and 6146 arc over has same negative effect (cathode resistors pop open) and if unlucky blown panel meter.

If you do only one thing I would put the diode string across the cathode resistors. This will limit the IR drop to no more than approx 2vdc.

KW attempted to fix the problem with blown panel meters with addition of R10 to the TS530/TS830 rigs. It is in parallel with the cathode resistors and when they pop it prevents the cathode from opening and rising toward SG voltage. That is big problem in the other models as open cathode will rise quickly to 125vdc or more and when you flip meter switch back to Ip position work the math of what current will flow thru the meter multiplier resistor and the meter movement. It is heck of a lot more than a 500ua movement will like to see. So you can experience a double hit. The arc over event and maybe 2nd hit when try to load rig again and flip meter from RF position back to IP.

Next time you pop cathode resistors on your TS520/TS820 series before replacing the resistors place meter off of the Ip position and then power radio and measure dc voltage from cathode pins of 6146 tube sockets to ground and watch what happens.

Depending on what production run 530/830 you have you can find R10 as 4.7k, 5.6k and 6.8k ohm. KW trying to pick a value that will hold cathode near grd potential while not affecting the accuracy of the IP reading too much. The higher the value the less impact on the displayed IP reading (simple ohms law for parallel resistors). In either case the accuracy is not effected much more than a needles width.

Anyone who was around in the day and remembers cathode keying on their novice transmitter knows what potential will be on your J38!

Hi Terry,

I wasnt sure if you had changed the design from two resistors to 1x. Ohmite does do 10ohm, in OY series, as I have 3 that I am using for another tube project that has a flaw in the design, it needs surge\glitch protection and am using 1x 10 ohm OY series resistor and 0.5amp fuse, to prevent damage to the HV and filament transformers and two 5 ohm OY series resistors and 1 amp fuse on SG. Just wanted to update my notes if you had change.

Happy Thanks Giving day to you and the family

Take care and keep warm

Dave

Louis

Eimac has a Hi-pot bulletin that details the procedure. Most important in my mind is to test from anode to cathode pins. Some short all the other elements together but not necessary on a 6146.

Some also test between Control Grid and Cathode. If you do this need to lower the test voltage level as it will break down at much lower level. May even see some glow in dark room with this test.

Ask yourself where is the shortest arc path? It is from Anode to Beam forming plates which is electrically the cathode. That is what occurs in most arc overs. How do I know? What fails? If tube arced to the Control grids (and it does on very rare occaisons. I have seen two or three cases) will see extreme damage to the -C path, bias voltage adjust pot, ALC transistor, molex connectors, back to -C supply return. Basically anything in the FG line including RF choke on the final board will likely be damaged. KW tried to fix this by adding a MOV to the FG line on the TS530 but never added it to the 830. I dont think it is necessary.

You have no control over the leakage current. It is limited by the Hi-pot design. Can see mine on my website at http://www.K9TW.com http://www.K9TW.com.

I short my test leads and bring up the variac until the panel meter reads 50ua. That proves tester is working and I am really hi-potting and not kidding myself.

I back off the variac and the dc voltage on the filter caps quickly decays. I turn off the hi-pot and connect plus alligator lead to anode cap and negative lead to Pin 1. I turn set on and raise voltage up to approx 1kv dc. Let is sit a second. I usually go up in about 500vdc steps while watching the ua panel meter. Stop at 1500vdc, then go on up to 2000vdc and stop. A bad tube the current will start to come off zero around 1000vdc and may start to bounce around or may just keep climbing from there. As I said in my experience a good tube will hold off 2500vdc (no ua leakage current at all).

Some people then shut down and reverse the positive and negative high voltage leads and repeat the test.

On high power tubes they do this to "burn off" conductive wiskers inside the envelope that are near bridging the gap between elements. We dont have any of that in the old 6146 tubes as they had near "clean room" manufacturing process.

Terry K9TW

I am using the 68 mfd 500V caps because I was able to buy 15 of them at less cost than the two 100 mfd 500V caps originally installed in the TS-520. That gives me eleven 68 mfd 500V caps "left over" to use on my other boatanchor projects - for example, an HP-23 power supply where I have recapped one old electrolytic (it blew up when I first powered it up) and where I am pretty sure I will one day have to recap the others when I get back to working on my HW-100.

Now let's do the math. Two 68 mfd caps in parallel give you 136 mfd. Two more give you another 136 mfd, which is more than the two 100 mfd 500V caps originally in the TS-520 give you.

People who are selling two 150 mfd 500V caps to replace the original 100 mfd caps claim that the greater capacitance gives you increased HV voltage over the original design. I am unable to determine if this is in fact true, and that is what I was asking.

Thanks, and Happy Thanksgiving!

Robert

I dont think it is so much about increasing the full load voltage as it is decreasing the ripple voltage. In my experience it wont improve the regulation under load.

Rough rule of thumb is double the capacitance value and cut the ripple voltage in half.

For voltage multiplier circuits you can use couple of formulas. Here is one to solve for the ripple and another to solve for the capacitance needed in the doubler circuit. You will notice they dont produce exact same results but I think close enough for back of envelope calcs.

Vrip = I x (Nsquared + N/2) / 8 x F x C Where I = load current, N= number of stages (we have two), F = freq in hz, C = capacitance

So with a 100uf capacitance Vrip = .250 x (2x2 + 2/2) / 8 x 120 x 100uf = 19.5v p-p or approx 20 volts ripple

Another formula to find the capacitance needed for a given ripple is:

With 19.5v ripple on 800vdc then C= 0.8 x I / Vrip x F

C= 0.8 x .250/ 19.5 x 120 = .2/2340 = .0000854 farads = 85.4uf

So you can see we get something between 85uf and 100uf to produce 19.5v ripple on 800vdc at 250ma load.

If you raise the 85uf capacitance to approx 170uf you will reduce the ripple to approx 9.7v p-p.

The ripple level that we have on our 900vdc anode supply seems high but it doesnt cause any presence of hum on our on air signals.

Maybe the EE design members jump in here and can shed some lite on the merits and maybe drawbacks of increasing the capacitance of the voltage doubler filter caps. Maybe surge current begins to become an issue?

I have been installing 150uf units for some time and have seen no ill effects and no negative feedback from the owners. I like original config and hate it when I get rigs with a tall metal can in one position or piece of perfboard with capacitor combos ty-wrapped or glued in place on them. If I was marooned on an island then anything would go. We all have differing amounts of discretionary income and free to chose how we spend it.

I have a 100:1 scope probe so maybe will get brave and put it on the top of the plate choke and measure ripple and try paralleling up additional capacitors. If you see a mushroom cloud you know I messed up!

Terry,

I was initially worried about that as well. Only thing that has caused me to investigate is highly repected tube amplifier guru's gave me a very well defined explanation and a heap of photos to show what happened with and without. The tubes at $US400 each is not something I want to destroy in a hurry hihi, but am still very cautious and still researching as well.

Have had a TL922 on the bench which had exactly that, both Anode and SG were fused. Still didnt helpthe band switch much when hot switching, but then again can lead a horse to water

Dave:

I forgot to include what Ian White has to say about fusing the SG. See page 6. I know that folks use fuses and block diodes in their homebrew Tetrode amps, but I think he presents good case why not good idea.

I did include MOV flashover protection for the Screen Grids in my protection mod and have installed in my two personal TS830s rigs, but most recently I have just been installing the diode string across the cathode resistors for the customers who want it.

50294. TS-520 Stopped Transmitting

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-28 02:13:23 UTC
From: dllewiszz@...
Topic: 50294 Message: 50294

My plain TS-520 that I use daily suddenly stopped transmitting. My HV is good but there's no drive, no Bias current, and no deflection on RF, ALC, or my external meter. Tubes are all warm. I can just barely hear my oscillator on another receiver, and can hear my voice audio in the noise. A few years ago I had a drive problem but my signal was quite strong on the stand-alone receiver (though there was no RF output to the antenna). This time it is much much weaker on the receiver. The TS-520 still receives great, and the weak xmit signal is on frequency.

What are the common usual suspects I should look for first? I haven't made voltage or signal measurements/traces yet. All guidance greatly appreciated!

Hi Robert,

I personally wouldn't consider doing that since there are replacements available, even though you have quite a few 68ufd 500VDC capacitors on hand. However, having said that, I understand that it's your TS-520 and your right to use what ever you think is necessary to replace the HV filter capacitors. Good luck and have fun.

Is the cutoff bias voltage on Pin 5 at 6146 finals tube sockets switching to operating bias level when you flip to Send?

Should go from approx -100vdc to -55 vdc.

Weak carrier osc has nothing to do with not being able to set zero signal plate current to 60ma.

Jan

See April 2012 for a tester for 3-500Z tubes. It is essentially a tester that has stepped anode and filament voltage. It is not a dynamic load tester. It reveals shorts and gas and allows gettering of the tube. It has separate filament and anode supply switches and plate current meter.

Here is an example of what I was talking about:

https://www.youtube.com/watch?v=Q6ZS83F0-uI https://www.youtube.com/watch?v=Q6ZS83F0-uI

Another thing to research is Pulse Testing of high power vacuum tubes. There are testers that use a high power FET to pulse the grid.

Have fun

Terry,
I have that QST issue and read the article many times to understand the issues that lead up to their design, and some things don't make sense to me. For one, if they are designing it to find flash overs in 3-500z, why do they build a huge capacitor filter, just like they are building one for an amp? Also, the grid circuit is strange to me, again they RF ground the grid with caps, again like building an amp? And then they place a "bias resistor" (?) on the filament center tap lead to ground, so any flash overs in the tube go right through the filament transformer (to take it out too?)
The 211 tube tester (don't know what a 211 is) features is some of what I wanted in my power amp tube tester and to include the 6146 tester too. Very interesting.
I found some highly regarded books on tube testers at Amazon, so I have them on order and I'll read them when they get here. So, I put the tube tester aside for now, and working on my Yaesu 901
Have you seen KF8OD's video on his hipot testing? Interesting.

Forgot to mention their filament PS is strange too. Why wouldn't one
just connect another variac to the filament transformer? So, instead of
a using a $50 variac, they use a voltage drop through the wire coils?
Also, they are not using a true RMS voltmeter to measure and set the
filament voltage for each tube. Just follow Tom Rouch's article on this
very important point:
http://www.w8ji.com/filament_voltage_life.htm
He just tears apart that guy's article in QST (I'm surprised QST
actually published it) about extending the filament life of 3-500z tubes.
(I wonder who are the technical editors for QST, if any?)

Jan:

By means of this video and the April 2012 QST article I am trying to show you the difference between a "Dynamic Load" tube tester and a tester that just energizes elements and "Cooks" the tube. It seemed to me that you and others were going toward the latter design.

I am not suggesting that the 211 tester in this video will test your 6146 tetrode, but a similar design with a screen grid supply is what you would need. Very easy to build in a transconductance feature to this kind of tester. Just place a 10 ohm or 100 ohm precision resistor in series with the anode lead and measure the IR drop across it with the control grid modulated. Inject a clean 1v P-P signal on the control grid and measure the IR drop across the precision series resistor. Now calculate the current with I=E/R.

As our tubes age they have less current available from the cathode. So you test a known good 6146 that has full output and lets say you calculate 10ma with 1v p-p on the control grid and you test another and it has 7ma you know it has lower "transconductance".

You could also build a dummy plate load with say a 25k ohm 100 watt resistor (maybe in oil bath).

Again all of this has to weighed against buying an old DX-100 or Viking II. With either of these transmitters you can dc test and apply RF drive. Just takes up a lot of room on the bench in the shop.

The latest testing of high power RF transmitting tubes that I am aware of is "Pulse Testing". This is done with a IGBT device pulsing the control grid. It is nice as needs no tuned input or output circuits. I have seen a couple of articles on how to build one of these, but cant put finger on it right now.

I am sorry for sticking my nose in. I just didnt understand why your DC hi-pot wouldnt be your tester of choice for a 6146 and then if it passes that testing put the thing in the KW rig and drive it with RF and see what its output is. Unless you want to run family of curves then you do need to build something like the 211 tester.

Ok then you are saying that you cannot set the resting plate current to 60ma.

Have you checked the two 10 ohm cathode resistors on the Final board?

Easy to access and measure with rig down powered and unplugged from the 120vac recept.

Jan:

Take a deep breath.

I am not a proponent of the 2012 QST article tester. I dont own any 3-500Z tubes. Again, I was trying to show you the difference between a "dynamic" tube tester for RF power tubes (a big boys version of a Jackson/Hickok which the 211 tester is) and a "cooker" type and a DC hi-pot.

I suggest you disregard my post and go back to your design that you started.

If it were me I would write down on paper what my testing objectives are and then see if the design you started will accomplish that. Of course when you get done might want to sit it next to a transmitter and see if you havent re-invented the wheel!

As you stated this is fun part of the hobby and shouldnt let anyone discourage you from trying your ideas.

I am moving on and no further raining on your parade!

Have fun

Terry K9TW

Terry,
I have tested many of my 6146s in the hipot tester, but how does one make any sense out of the leakage current. They all seem to follow the same leakage response vs high potential . I don't think I remember any of them exhibiting a flash over. So, I wonder where does one draw the line on what's best, good and bad.....using the hipot tester?
So, I went on to build the emission tester, and test the tube as a diode. There, I can see a difference between known 6146s that put out the highest power (the "best" grade) and just average ones (most of the tubes) and I must say, dead ones (I found one in the emision tester).
One interesting test was a hipot test on a new Russian GS-35B tube of mine and I ran the potential way up, and I could hardly see maybe 1-2uA of leakage. I thought, wow, its so low it has to be very good.
I did some tests on my collection of (used) 4CX1500Bs and they exhibited some leakage (I don't have the numbers here in front of me) and was puzzled again about what is the best/good/bad?
Does it seem that I need to conduct a lot of measurements to build up some statistics on a bunch of tubes?

50310. Hello! Newbie Hybrid Owner - TS-830S, No Modulation

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-28 18:58:44 UTC
From: viragoxv@...
Topic: 50310 Message: 50310

Hello from a newbie hybrid owner!

K3MG turned me on to this group, and I wanted to say "Hello", and ask a question...

The TS-830S that I recent decided to put back on the air was operating "OK"; that meaning within my very limited knowledge of the radio's functionality. Signal reports were fine, even though I may not have been outputting at full power because of my confusion regarding how to tune the radio properly.

It was suggested I check the resistors on the RF board before going too far with operating the radio. I dutifully removed the covers, the high voltage cover, assured the caps were discharged, removed the two power tubes, removed the 7 screws holding in the RF board, loosened the two wound leads closest to the radio's side, and leaned the RF board down to inspect the resistors. Seeing no signs of burnt resistors, I rewound/replaced the two leads and secured the board.

After doing this work, I tightened a loose Band Switch coupling set screw, and sprayed the Band Switch discs (scratchiness hear when changing bands) and AF/RF pots (volume would drop off by about half sometimes, recovering when the AF knob was twisted back and forth). I reassembled the radio.

Testing found the Band Switch worked fine, with no looseness or scratchy sound. The volume drop-off was greatly improved.

Unfortunately, I had no modulation when I tried to transmit on 40M. I checked the tuning and it seems fine. When the MODE switch is in TUNE or one of the CW modes, I had output when I flipped the REC/SEND switch to SEND. Similarly, when I pressed the PTT switch on the MIC (Shure Model 444) when the radio was in a CW mode, I had output. Likewise, when in LSB mode, I hear the TX relay move when I press the Mic's PTT switch.

Though it's possible something went wrong in the Mic JUST when I did the "repairs", the consequence seems a little "much" for me; I think I screwed up something inside.

Thus far I've assured the radio was set-up properly; the rear SG switch is on ON; I went back in and soldered the RF board leads I had only rewrapped; inspected the Mic wiring and Mic socket's radio side connections; and inspected everywhere I had my darn fat fingers! Still no modulation.....

I removed the top/bottom covers again and reinspected, but nothing seems out of place. My course of action at this point is to try another mic if I can borrow one, and if that doesn't work, send the radio to someone who's better equipped than this partially color-blind, fat fingered Monkey....no offense to Monkeys!

Any thoughts gang? Thanks in advance! Mike, N3QIG

OK then need to measure the screen grid voltage at the 6146 tube sockets Pin 3 with rig flipped to Send and lastly measure the Anode voltage at the top of the RF plate choke inside the PA cage. Your owners instruction manual has a table that contains the tube voltages in Rx and Tx modes and you will see the SG voltages listed.
You will need a VTVM or DMM with good condition test leads and a 1000vdc range to measure the plate voltage. This must be done safely.

One way is to connect negative lead of meter to chassis ground and use one hand to apply the red probe tip to top of the plate choke while observing the meter. Actually I would measure at the the suppressor lead at the end nearest the phenolic anode cap as on rare occaisions the solder is sublimated at top of the choke and best to make sure have 900vdc at the end of the suppressors.

The other way is with rig turned off connect the voltmeter black lead to chassis ground and connect the red lead to one of the parasitic suppressor leads (if you dont have an alligator probe tip adapter you will need to use a alligator jumper test lead or mini-grabber test lead and must make sure it is securely connected on the suppressor lead and the meter red probe tip. Dont want it to pop off.

The junction of the red probe tip and the alligator lead must be well in the clear and perhaps covered with insulating material so you dont accidently forget it is there on the bench and brush against it, place meter on 1000vdc range, and then make sure you are completely in the clear and turn on the radio. No need to flip to Send should see close to 900vdc on the meter. Immediately shut radio off and do not remove jumper leads from top of choke or off the red meter probe until HV filter capacitors have bled off.

You have said that the filaments are lit and you have good operating bias and the cathode resistors are good. Only thing you then need for plate current is SG voltage and Anode voltage when you flip to Send. Of course you also need a good meter and meter circuit and you have said you see no RF output on an external wattmeter so it is most likely that the meter circuit is good. If you report back good SG and anode voltage then I will ask you to recheck the heaters and then can go on to look at the meter circuit.

If you have bad HV filter caps this could be the root cause. You can check the 900vdc by placing rigs panel meter in HV position with rig in LSB or USB and mic gain turned down and flip to send. The problem with this test is it tells you that you have 900vdc at the HV caps but not if you have it at the parasitic suppressors. If you want to do this test first go ahead. If it shows nothing or 450vdc then no need to test at top of the plate choke with your voltmeter as you have bad HV filter caps. Sometimes can tell by looking at the rupture vents but really need to ESR them.

Terry K9TW

Hi group: Recently purchased this KW on e-bay. Rig was listed as receiving-xnmt not tested. As always, removed the covers to see what I could see. What I saw was the cleanest TS-830 I have seen. I mean there was not a speck of dust anywhere on the interior of this rig. Opened the final cage and everything looked the same as far as clean . The first thing that jumped out at me was the 6146b's had been replaced with w's. After powering up I did get some reception and after rotating the band switch a few times got good reception on 40m. Trying to tune up in tune mode I got no alc initialy, but after a few minutes did get some alc. I am going to proceed with testing and don't want to take up any more time on this post. Does any one have any idea how old this rig might be? Thanks guys Ron KD0KPM

Jan:

As I have mentioned couple of times a "good" 6146 in my experience will hold off 2500vdc (anode to cathode). That means ZERO ua leakage current. None at all.

Many will hold off 2000vdc with ZERO ua leakage and probably OK to use those. I prefer to have a little more head room especially if I have no arc over protection in the radio which no original KW radio has and many folks dont want to install the mod.

You should most commonly see one of two ua indications that tell you tube is arcing over or breaking down (at these voltage levels wont see any dazzling arcing display inside the envelope with perhaps exception of in a very dark room?). A. Meter will start to flicker at one of the voltage steps coming up. It may bounce up scale and go back to zero at the same step voltage and if it does it just arced over. OK to continue on up. B. At one of the voltage steps the meter will slowly start to come off zero and keep going up as you raise voltage or may level off at some leakage level like 20ua or so and wont go any higher as you increase voltage. The indication of leakage current typically will start around 1000vdc and once in awhile lower. Neither A or B is "normal" for a good tube.

However, you may be able to place a tube with condition A in service and have no problems just the same as many people will try their finals again after an arc over and replacing the cathode resistors. I admit having done this in the past, but that is before I understood what was happening and had to replace a panel meter. I wont use the tubes again if they popped the cathode resistors.

I dont want to challenge my panel meters in my personal radios not to mention my HV caps, HV rectifiers, and Power Transformer with that tremendous amount of fault energy any more. Also, I dont want to lift foils on the Final board (you should see the junk soldering I see on that board) and frankly a pain in the butt to have to repeatedly remove covers and fold over final boards and replace cathode resistors.

The problem with an emissions tester or transconductance tester that I am familiar with is it is NOT replicating the RF voltage swing at the plate of the 6146 tube in service. In this case approx 1600 volts.

So YES you can certainly sort tubes by emission or transconductance testing and you will find tubes that are softer than others, but it tells you nothing about whether it will arc over with RF drive. So you sort your 6146 tubes by how well you could load them in your tester and you select the "good" ones and install in your rig and load it up to 110 watts out at 225ma (as opposed to 90 watts with the lower emission tube) and all is well until the next time you flip to Send and hear a sickening Pop and if your eye is quick enough see the meter peg!

So you DO need both tests and the way I do that is to run the tubes in the rig after passing DC hi-potting. Our rigs are our emission testers and transconductance testers and none better than the rig for this purpose in my opinion. As I said the sub is to use an old beater DX-100 or Viking II or similar to do the emissions testing where you dont care about

damaging it. Again if you want to build an emissions tester of some design have a ball just make sure it is current limited and has a very reliable bias supply as you still have the 6146 Plate and Screen grid dissipation maximums to deal with. Thermal runaway usually destroys 6146 finals very quickly. I have a box full of 6146 finals with melted and sucked in glass envelopes and holes melted in the anode (black plate).

Yes I am sure it will take time to tell what is acceptable DC hi-pot ua leakage with many high power transmitting tubes especially when you are testing at 15kv or higher levels and then may see effects of humidity and leakage across envelope and external structures. Maybe even a low level of leakage across the tubes internal elements support structures is acceptable on some mfg tubes? I have ZERO experience hi-potting high voltage high power RF transmitting tubes. Could only go by what Eimac or Burle of other mfg published specs.

These are getting way too long. Maybe we should take this off the reflector?

Since my HV meter shows OK, I went straight to the SG measurements and found nothing. Before going to the anodes on the finals I decided to look for the cause of no SG, and went straight to the power supply. I am seeing no voltage at 210A but 210B looks fine. I did some in-circuit resistance measurements (after bleeding the caps) and I see a solid 500 ohms to gnd on 210A, while the other caps (C27a/b and C28a) show a substantially higher resistance especially in reverse (positive on gnd). Before pulling the leads off the cap, I'll ask is the culprit likely to be the 22uf filter cap? Or, since the other side of the cap is doing fine, is there likely something else pulling down the 210v line?

Many thanks for the guidance, Terry. If the cap is bad I'll be asking about the best source, and ... wow, it doesn't look too easy to get to with all the other boards mounted around it.

The 300 and 210 caps are mounted on the back right corner of the IF board. Ken K4EAA sells a kit of 4 of them. These form a C-R-C pi-filter with 470 ohm series resistor elements. One resistor is on the HV rect board and another is beside these 4 caps. Look at both to see if dark or discolored and if so replace both.

If you pull Molex conn 14 and 15 to isolate the caps you should read something on the order of approx 50k ohm to grd at 210A. I would do this test first to prove the fault is due to leaky or shorted filter capacitor.

I would pull the IF board to replace these 4 filter caps and not try to fold the board over. Becareful pulling the connectors. Dont rock them side to side as you pull. Pull up straight and if stuck then while applying upward force rock end to end. Side to side rocking can induce a hair line crack at the pin pad to pc trace transition area. Hard to troubleshoot. If this happens have to clear off mask and try to drag solder across or install small jumpers.

While board is out carefully under good lite and magnification inspect the soldering at every Molex connector Pin pad. Very common to find the pin floating and cause of poor performance/intermittents.

Take picture of the connectors or make a drawing before removal.

I need to move on as you have this well in hand.

Dave,

From what you have said, 210A voltage is 0VDC but 210B voltage is okay, have you checked R6 on the Rectifier Unit?

If R6 is open there will be 0VDC found on the following locations

1. Rectifier Unit 210 terminal
2. HV Unit 210 terminal
3. RF Unit 210 terminal
4. Final Unit SG terminal

This will lead to the following symptoms:

1. No RF output from the driver tube (driver tube is shut OFF even when the filament is glowing due to loss of screen voltage)
2. No ALC indication during DRIVE control peak adjustment in TUNE mode regardless of the CAR control setting due to loss of RF drive from the driver tube
3. No final amplifier IP idling current in any mode due to loss of positive screen voltage (adjusting the bias pot will have absolute no affect)
4. No RF output from the final amplifier

You can see this on the TS-520 schematic found in the operator and service manuals.

I am sorry I think I gave you info for a TS830 and not a TS520!

Apparently you figured it out. Yes the 300/210 caps on the 520 are a little tough to get at. I replace them with Richies Golds out of Canada. A little pricey but a nice fit.

Yes always good idea to question why and to try to determine the root cause of a failure. Sometimes components just get tired and fail. Carbon composition resistors are also hygroscopic so common for them to go high in value and even fail open. If not discolored and found open that is probably the issue. If darkened then current was the problem and good idea to do some checking to see where source of higher than normal current is.

You can measure the IR drop across R6. Then calculate the dc current thru it with I= E/R. Then calculate the power with P = I squared x R. Once you know that you can see what R6 is dissipating.

It sees screen grid current, screen grid divider current, STB divider current on it (been awhile since I looked at it so you need to study the schematic and identify the current sources and then can get a pretty good estimate of what current R6 sees). Other way would be to lift 210 wire wrap termination and place current meter in series with the lead wire and the post, but I wouldnt do that.

I may have "normal" R6 IR drop in my notes?

Dave,

You're welcome. I'm glad you found R6 open since that was the only component that could cause loss of 210A voltage which, as I said, is easily seen by studying the TS-520 Rectifier Unit schematic.

A bad C28A (22ufd 450VDC) cap could easily cause R6 to burn open.

Mike:

I agree R6 is the most common component to fail, but not the only one.

Can also have a bad SG switch (case tabs bent back and movable contact guts hanging out), or a poor solder connection or lead broken off the SG switch, an open L4 choke, and open grid stopper resistors. Have seen them all.

In my opinion the 520 schematic is the worse one to be able to see things easily due to non-conventional way it was drawn and the parallel line density especially if working from the one in the owners manual. I have a large blown up schematic and often have to use a straight edge to follow AGC, ALC, SG etc. Of course my eyes arent what they use to be!

I recommend that owners who want to work on their 520 go to Staples and have them digitize and blow up the schematic. Even an 18 x 24 will help, but a 24 x 36 now your cooking! I even had them laminate mine.

Aaron,
The AT-250 can be used with any Kenwood. If you use it with the TS-830S, the "AUTO" band selection is not available, and thus you do not not, or can not use the "cable." You must select the band manually..and follow the manual for proper connection of coax and operation of the tuner. You can download the operation manual at:n6wk "dot" com and look down all the available files until you come to the AT-250 manual 73 Joe

Joe,

Thank you for your reply!

The snippet of the AT-250 Operating Manual that I pasted into my message did not show up correct.

I understand that the AT-250 can be used with my TS-830S, and that band selection must be use manually, NOT in the AUTO position.

My question is regarding the need for the remote cable between the radio and tuner, as shown in the operations manual picture of a 830 hooked to a 250. I do not use any such cable when hooking my MFJ-993B tuner to the 830, and everything works fine.

I'm curious if I need to use a cable with the 830/250 combo for some reason. I tried hooking up the 250 to the 830 without the cable but the 250 made no attempt to match the radio/antenna....it just sat there! ;-)

Any help would be greatly appreciated! Thanks! Mike, N3QIG

Oops - Mike, I called you Terry by mistake. You've both been quite helpful. I've looked around at the SG switch and at the rectifier board and don't see anything unusual. Since the rig was working properly and then stopped transmitting, it is less likely that mechanical problems caused the failure, and more likely that R6 just went open due to age, or that C28 helped it along. I'll pull the leads off two of these caps and compare resistance readings in both directions and will note the charge action on both to try and determine if the cap is defective. I'm seeing about 500 ohms across it on an in-circuit test but that isn't proving anything. It looks like R6 is a 2 Watt resistor. If that's not correct, please let me know -- otherwise, you may drop this thread from your radar screens while I get some parts and get back on the air.

Thank you again, gentlemen!

The parts list shows the Rectifier Unit's R5 AND R6, both 470 ohm, are
"2 watt". If I said "1/2W" then I was wrong.

I'll back down and let you and Terry continue

Stephen:

I think have pretty well covered about all I can contribute to dc hi-potting of 6146 tubes. I have a write up on my website http://www.k9tw.com http://www.k9tw.com under the How to Guides and couple of pictures of my hi-pot. I will be glad to try to answer any questions you may have off list at this point.

I am likewise confident that Jan would be glad to discuss his work on the emission tester he is building.

Only thing I would like to close with is that in my experience there is still no better test than running any 6146 tube that you have in your specific KW hybrid. I dont know of any test gear or testing techniques that can give you 100% assurance wont have a failure in service. About best we can do is cull out the weak sisters.

Appreciate your interest.

Terry K9TW

I have a 390 ohm / 2W in the resistor box but figure that's not close enough, so I'll stop by RS and hopefully pick one up. I have isolated the caps (and all the 210 feeds) [remember when we used to call this B+ ?] and determined they look good, but the 500 ohm load from the driver board still gives me some concern. The 210 connector on the driver board feeds the driver tube via a 3900 ohm series resistor, but I'm reading substantially less than that, and am seeing lower than expected resistance from pin 8 of the driver to ground. The .01 cap looks good visually but I suppose could be shorted or exhibiting low resistance. We'll see what happens with the new R6 and I'll look closely at the drop across that resistor to determine the current flow and power dissipated thru it. It's possible something is going on with the driver ckt.

Topic: 50325 Message: 50337

Mike,
I have some computer problems going on...so..I'll resend:
I looked around, and it appears that the tuner needs a keying signal.
From what I can figure:
 On the rear of the 830S - REMOTE socket...pins 2, 4, & 5 need to be connected to the AT-250 "ACC" socket pins 2, 4, & 5. This will be a pin for pin connection....pin 2 to pin 2...etc.
Please check both schematics to see if you concur. I am away from home..and looking at a real small screen...and enlarging just gets all pixelated.
I don't want to give erroneous info..and have you fry something!!

  Joe,

Thank you for your reply!

The snippet of the AT-250 Operating Manual that I pasted into my message did not show up correct.

I understand that the AT-250 can be used with my TS-830S, and that band selection must be use manually, NOT in the AUTO position.

My question is regarding the need for the remote cable between the radio and tuner, as shown in the operations manual picture of a 830 hooked to a 250. I do not use any such cable when hooking my MFJ-993B tuner to the 830, and everything works fine.

I'm curious if I need to use a cable with the 830/250 combo for some reason. I tried hooking up the 250 to the 830 without the cable but the 250 made no attempt to match the radio/antenna....it just sat there! ;-)

Any help would be greatly appreciated! Thanks! Mike, N3QIG

Dave:

Ohm-meter testing of the electrolytic filter caps is not a very good way to test them. Best in-circuit test is to ESR. Absent that tester then use something like a Heath IT-28 or better yet a Sprague Tel-o-Mike and measure leakage current. If you have a variable HV dc supply can use it with your DMM on dc current range to measure leakage. Lots of opinions on acceptable leakage limits but a rough rule of thumb is 1ma/30uf.

Also eyeball the rupture vents and if swollen and cracked time to replace them. Ohm readings and watching charge or measuring capacitance with a bridge wont tell you very much. Can still have capacitance value within tolerance and be bad.

Good 900vdc HV caps will ESR around .30 to .40 and good 300/210 caps will ESR around 1.0 to 1.5.

Very common for screen grid divider resistors R70 and R71 to be bad and sometimes changed out as part of QRO mod. Most commonly will find R70 82k to be bad and frequently it will be open.

R6 is used in lieu of a choke coil as it is cheaper to use a C-R-C filter than a C-L-C filter. Ken K4EAA sells a kit that includes R6.

Here are some typical 210A readings measured from the 210A wire wrap post (rig down powered).

1. Approx 71k ohms to chassis ground
2. Yellow wire = approx 175k to ground
3. Orange wire = 122k to ground
4. The Yellow wire and Orange wire loads are in parallel or 175 x 122 / 175 + 122 = 71k

The Yellow wire feeds STB on the AF Board thru R16/R17 100k dividers mounted on a phenolic terminal strip near 6146 final tube sockets. R16 and R17 are shown on the schematic just below the Indicator Unit. Never found them bad.

Dave

I dont have covers off a TS520 at this time. You may want to contact Jimmy Lamanteer WB2KNR. He is the TS520 guru and has a fleet of 9 or 10 TS520s at all times and usually has covers off and you might get him to take some "normal" readings for you. What I have given you is from memory and some notes but not recent.

50341. TS-520: Intermittent Xmit Audio on 15 Meters

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-29 23:24:54 UTC
From: mike.allard42@...
Topic: 50341 Message: 50341

Greetings! As a prelude: I posted about three weeks ago noting that I had a bad solder joint in my new-to-me TS-520; I was able to fix it (along with another one that I noticed on another air variable capacitor contact) and my jumpy meter seems to be fixed. I also used DeOxIt on all the switches and pots, and my dirty volume pot is much better.

Before I fixed the radio, I had a couple contacts on 15 meters. Each of them noted that I seemed to have some audio issues; one guy talked with me long enough to describe what he was hearing. He said that when my audio was working, I was 59+10; when it "cut out" it sounded like I was talking from across the room. One of my elmers said that it sounds like a cold solder joint.

I have made other contacts on 10, 20, and 40 meters, always with excellent audio reports and often with comments about how good the mic sounds.

When I watch the ALC meter when I'm transmitting on 15; the needle behaves "normally" for a second and then slowly fades, and then it may (or may not) jump back up again. Also, it seems like the MIC control needs to be set much lower on 15. I typically have it set at about 5; on 15 meters, I have to set it at about 2 or so, or the needle swings way past the ALC range.

Note: I am not an electrical/circuit expert, and I'm still learning how radios actually work under the hood. I can read the schematics and can follow directions, though. :) I do have a Heathkit IM-13 VTVM which seems to be properly calibrated, so I can take some voltage/resistance measurements.

So: Any suggestions on where to look? 15 has been open in the early afternoon; I made "most of a contact" with a guy in the Canary Islands off the end of my 40-meter dipole yesterday - but he could never pick up the last letter of my call sign. Sigh. I'm really excited about making some more DX contacts!

Thanks in advance - I've been enjoying reading all the great messages for the last couple weeks and I've saved about a dozen for future deeper research.

You're spot on, Terry. The big surprise right now is that R70 reads 200 ohms and R71 reads 300 ohms. With nothing else in the ckt! That is why I kept seeing 500 ohms to ground on 210A. When I pull 210A from the driver board I see the approx 70K resistance to ground that you describe (on the 210 line). Both R70 and R71 have been warm, with the colors faded and some slight cracking observed. It's unusual (to me) to see two resistors age and drop to a pretty low resistance compared to their original spec (82K and 3900). Man, it's not easy to get to the underside of the driver board.
A new R6 and new R70 and R71 tomorrow and my bet is that I'll be on the air unless the driver tube is defective. With R70 out of ckt and 210A reconnected to the driver board, and the tube in socket, things appear normal on the 210A, so at the very least I shouldn't burn any more R6's after these parts are replaced.

Dave:

Yes pretty common to find bad SG dividers on all the Hybrids. I stock a large supply of the resistors. Depending on the model either a 82k or a 100k is used in this application for slightly different (a little lower) driver tube sg voltage.

You may have a bad Driver tube as the values of this divider may have resulted in too high voltage on the SG and exceeded the SG dissipation rating (it is only about 1 watt).

I dont think I see a single TS820 where these same dividers are not bad. Its RF board is very easy to pull and need to pull it anyway to clean the molex connectors at the Coil Pack board interface so as a matter of routine I just pull the Driver tube anode supply resistor and the two SG divider resistors and replace all 3 of them and with the board out it gives me easy access to the VFO air variable access panel cover screws to let me do a good rotor shaft wiper contact cleaning. Some fellows bugger up the two screws and scratch the aluminum plate with a needle nose pliers and cross thread the two small screws. I know you dont care about the TS820. Just telling you and others that your issue is not limited to the TS520 design.

OK when you get all done make sure you measure not only the Driver tube anode and screen grid voltages at the tube socket but also measure the 6146 screen grid voltages at the tube socket. Need to make sure someone hasnt performed some goofy QRO mod. Most common is to supply 6146 screen grids off the 300 bus. If you are going to do much of this work suggest you buy a Pomona test socket for the Driver tube to facilitate voltage and signal measurements.

You have this well in hand and I need to move back to the bench.

Have fun and be careful

Topic: 50341 Message: 50344

Try changing the Driver tube as first step.

Can also test the RF drive level on all the bands by turning off the SG switch and with rig in CW mode flip to send and adjust Car Level for max ALC and watch the key down level to see if it holds where you set it. Do this on all bands and let it rest a little between bands. 12BY7A cathode emission begins to fall off on the higher bands as the tube ages.

Jeremy,
Look on the rear of the rig and make sure that there is either a small round 9 pin "shorting plug" as referred to in the operators manual, or a piece of wire making a jumper between pin(holes) 8 & 9. If either are there, with the display blank, does the rig seem to operate otherwise??If either/or are missing there is no power to the VFO...thus rig won't work
If on or the other are there, you may have to pop the top and possibly clean the connector on the top of the DG-1. That is the rectangular box that is connected to the digital display tube.
The 820S is a great rig, but the DG-1 unit is a real problem at times.

50347. Kenwood Hybrid Net Update (November 30, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-11-30 19:46:45 UTC
From: Mark Gilger
Topic: 50347 Message: 50347

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There
were 36 stations checking in under good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
5 running TS-530(x)
2 running TS-820(x)
7 running TS-830S
0 running TS-511
0 running 599 twins

I was running my Drake 'C' liine & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
20 stations checking in under fair band
conditions. He had the following number of radios checking in.

2 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
6 running TS-830S
1 running TS-510
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my Drake 'C' line & Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Terry -

I did the RF drive test as you suggested, leaving it in Send for 10-15 seconds on each band, with at least 1 minute delay between bands. I did not see the ALC meter start to drop on any band, even on 10 (which is where I understand the driver tube will first go "soft").

Then I tried to tune up the radio on 15. It only took me about 30 seconds to remember that the SG switch was still off. :)

I was able to make a contact with PY2VI in Brasil on 15 - and a couple hours later I had a 5-minute QSO with KB7MBI, Alan, in Seattle. He told me that my audio sounded great, and that my D-104 was a great complement to the TS-520. (I'm running the D-104 unamplified.) And then the band faded on us.

So, at this point, it does look like my intermittent problem might actually be fixed. And it looks like maybe my driver tube isn't on its last legs yet.

If the problem reappears, I'll probably be back with more questions!

Thanks so much, and 73!

- Mike, K9MJA

Just want to let everyone know that Radio Shack is currently offering Caig Silver Conductive Ink pens for $12.47, which is about 40% off regular price and easily the best price around. Use the code CYBER10 at checkout to get an additional 10% off. Shipping to your home is free.

This is the product that Ken, K4EAA, recommends for bandswitch repair.

The link on to product on the RS site is:

Joe,

From the manual, it looks like I need one 7-pin and one 8-pin DIN plug, and some shielded two conductor cable.

On the 8-pin plug for the AT-250 ACC socket, the shield is grounded and pin #8 and #3 are used. On the 7-pin plug for the radio's REMOTE socket, the shield goes to pin #2, and pin #4 and #7 are used.

```
AT-250 ACC Radio REMOTE
Pin #8-----------------Pin #7
Pin #3-----------------Pin #4
```

I'll like you know how I make up after the parts come in.....73! Mike, N3QIG

thanks for the info about my 830 display. Bob put me right on it. I took the top off and reseated the 12 pin molex connector on the display board that didnt fix but i noticed i could apply pressure to the connector and everything returned to normal. it had a cold solder joint on the male part of the connector soldered to the display board. resoldered all the connections and everything Ok. You folks are the great!!! Jay N4HD

50360. TS-520 meter lamps in series or parallel?

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-02 02:48:20 UTC
From: dllewiszz@...
Topic: 50360 Message: 50360

One of my lamps is open and I don't know if they are factory/original or have been replaced. I understand the originals are 12V/50ma but how are they wired originally? Mine are in series with a 47 ohm resistor between them. Whether I buy a pair from Ken or elsewhere, I need to make sure I wire them correctly - and whether or not the 47 ohm resistor is original or a later mod.

Dave, WA4FXT

50361. Re: [TS-520_820_530_830] TS-520 meter lamps in series or parallel?

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-02 14:14:45 UTC
From: Mike W5RKL
Topic: 50360 Message: 50361

Dave,

The 4 lamps (meter and VFO) are wired in parallel. The lamps are all 12 volt lamps. The original lamp circuit does not have a resistor in series with the lamps. The lamp power is provided by the TS-520 power transformer's "12.6" secondary winding. The lamps are very easy to find on the TS-520 schematic, they are labeled PL1, PL2, PL3, and PL4. Ken, K4EAA, sells replacement 12 volt lamps. You do not need the series resistor.

Dave,
The answer is YES. It uses the same bulb and mounting method as in the rigs main VFO, as they are the same.
The bulb is also the same as those used in the 520, 820, 530, 830 meter and VFO illumination 73 Joe

Topic: 49713 Message: 50365

Yes, David, there is one lamp in the VFO-820. You can see it on the VFO-820 schematic, page 71 in the TS-820 service manual. The lamp is labeled "PL1" and it lights the VFO dial, same place as the TS-820's internal VFO dial lamp is located. It's a 12 volt lamp, same as those in the TS-820 meter and VFO dial. The lamp receives power from the TS-820 through the remote VFO socket, pin 4. Ken, K4EAA (www.k4eaa.com), sells replacement lamps for the various KW hybrids (see his website for details and prices).

Mike,

I finally got around to pulling the cover off of the finals today and was surprised to find that they are S2001As not 6146s. I was aware of the old 6146 and 6146A "in the old days" , and I know that the Bs are slightly different. The S2001A is a curve ball to me.

I have checked around and they seem to be equivalent to the 6146B, but don't seem to be carried by any of the three places you recommended. I can't seem to find more than 1 S2001A from any one source, but I did manage locate Sino 6146Bs from Tube Depot.

You be the expert here. Is that what you would recommend?

Tom,
The Matsushita S2001A final amplifier tube(s) came as original equipment until sometime in the mid to late production run of the TS820S series. They are now considered "obsolete." My 820S still has it's 2001A's and they still have very good output. I know nothing of the Sino brand. The 6146B and 6146W are good replacements...as to the brand...that subject has been "discussed" at great length...so, I will not recommend a specific brand...but, I stick with a "USA" manufactured tube. That's just me. There is a good document regarding the 6146 family of tubes in the "FILES" on this groups home page. 73 Joe

Hi Tom,

The S2001A is the Japanese equivalent to the 6146B.

The "S2001" is the Japanese equivalent to the 6146/6146A. Notice the lack of the "A" suffix!!

There are a few differences between the 6146A and 6146B tubes

1. Plate dissipation is higher in the 6146B when compared to the 6146A
2. 6146/6146A Grid #1 to Plate inter-electrode capacitance is .24uuf while the same inter-electrode capacitance in the 6146B is .22pfd, a difference of .02uuf
3. Filament current in the 6146A is 1.250 amps at 6.3VAC while the 6146B filament current is 1.125amps at 6.3VAC

The 6146 is the exact equivalent to the 6146A except the "A" has a more rugged filament.

The 6146As are still in use today in other makes and models of vintage transceivers/transmitters. The 6146A can be found as NOS tubes at various on-line websites such as:

www.vacuumtubes.net

and

www.TubeDepot.com

to name a few. There are others but those 2 comes to mind.

I don't know what condition my finals are in. They "look" brand new but I bought the rig at a hamfest last June and so I don't know and have no way to test them. I am returning to Amateur Radio after a 26 year hiatus and have almost nothing in the way of test equipment any more.

The problem with the rig is that the two 10 ohm cathode resistors have blown (apparently NOT for the first time because they are obviously NOT original) with no other visible problem. At this point I am thinking that I will replace the resistors and see what happens. If they blow again, I try getting new finals.

Hi Mike,

We have discussed my problems the rig before . The obvious problem with the rig is that the two 10 ohm cathode resistors have blown (apparently NOT for the first time because they are obviously NOT original) with no other visible problems. I'm still don't I understand why they popped.

I briefly considered just replacing the finals just to eliminate them as a problem until I started having trouble finding a pair.

I understand the difference between the 6146, 6146A and 6146Bs and understand that you can swap the first two without question but that switching to the "B" can cause problems because they are really a different tube internally with differences in inter-electrode capacitance, etc.

My rig has two S2001A that "look" brand new (I have no way to test them). That implies that the "B" is the preferred replacement. I can't seem to find two S2001A from any one source and have only found one source for the "B's" and they are some Chinese brand (Sino) that I have never heard of. Internet chatter paints the Chinese tube in a bad light. I hate to drop $50+ on junk tubes.

At this point I am thinking that I will replace the resistors with some 3W Metal film jobs (i.e. non-inductive) and see what happens. If they blow again, then I guess I'll try getting some new finals.

Tom,

You seem to be convinced you have to find two S2001A final tubes. That's simply not necessary!! As I said, the "S2001A" is the Japanese equivalent to the 6146B!!!

You can simply replace the two S2001As with two 6146Bs, neutralize the final amplifier by following the neutralizing procedure in the operator or service manual, and you're done!!!

You will need a VTVM with an RF probe, a 50 ohm dummy load and the transceiver's operator or service manual.

Tom,
I agree with Mike. You do not need to find the S2001A's. A couple of good tube suppliers, Mike has already mentioned. 6146B or 6146W will fit the bill and, as Mike stated, you will need to neutralize them after installation.
I will also caution you about installing the 3 watt resistors you mentioned. There are several reasons that the cathode resistors may "pop." Internal short in one or both final tubes, operation with way high Ip, long operation in an "out of tune" condition.

Since you stated that you got the rig at a ham fair, you do not know the history of said rig. I would go over the rectifier/transformer wiring to see if any of the wires do not match the schematic...ie..a possible QRO mod. Also, check for the correct value of the 470 ohm screen resistor on the rectifier board.
Sorry for jumping in

Topic: 50325 Message: 50375

OK, I made up a cable as described above. The pin-out was taken from manual, for transceivers other than the TS-430. The tuner still doesn't make any effort to tune-up.

PLEASE NOTE: The manual's cable pin out connections are shown as the radio and tuner sockets are viewed from the rear of each component. This logic would be the same as the pin-out for the cable connectors as viewed from the rear where the wires are soldered.

Using this logic, I clamped both connectors in a vise, both "key-ways" at 12 o'clock, with the solder ends up, and soldered the wires per the manual. Once complete, I checked the work with a VOM, and it wrung out fine.

I'd love to hear suggestions! BTW, my MFJ-993B tuner works GREAT with my mini-G5RV and the TS-830. The thing which REALLY bugs me is that the AT-250 doesn't make ANY effort to tune-up.

Thoughts? HELP PLEASE!!! 73 Mike, N3QIG

Tom,
I see no reason that they should not be 'ok.' Just buy from a dealer/seller that allows returns if they may prove defective. Just havesome more cathode resistors handy...hihi. Many people are using non made in the USA tubes and are quite happy

Tom:

I didnt see anyone who really answered you as to "why" your cathode resistors failed apparently more than once.

It is not too hard to figure out.

I have seen the suggestion that if you run high duty cycle modes without lowering Ip that they can fail. I have seen the suggestion that if you routinely perform high off resonance key down times that they will fail. These place the blame on operator error or practice and I submit not very likely. In fact almost impossible.

You can prove that by placing a resistor on the bench and applying 250ma thru it and watching for change in color or for it to begin emitting smoke. You are going to have a very very long wait. Now if you lose the operating bias on the control grids (say it is Zero volts) your IP meter will peg. If you look at the 6146 family of curves you will see with G1 at Zero volts you will have approx 400ma plate current. So increase your current thru the 10 ohm resistor on the bench to 400ma and walk away. Again you will have a very long time if ever for that resistor to fail. Yes it will change value, but you wont see a failure.

P= I squared x R so at 250 ma your cathode resistor will be dissipating .250 x .250 x 10 = .6 watts. So a brick on the key at 250ma IP is not going to cause any distress to your cathode resistors. I will let you work the 400ma case.

I respectively submit that the two purported failure modes provided to you just dont happen. Carbon composition resistors commonly fail in two ways. One is acute failure and the other is chronic. Carbon composition resistors are hygroscopic and they can simply fail due to age. Moisture intrusion causes them to change value and sometimes go to infinity. If old enough the carbon material to lead wire fused interface area can become corroded and go open circuited. This doesnt happen very often with the Cathode meter shunt resistors. I have seen them as high as 8 or 9 ohms, but only time open was due to an acute failure. Inspection of the body will reveal a crack to prove that.

Now lets talk about acute failure. Remove the 10 ohm resistor on your bench that has been cooking for weeks with 250 ma dc load current and take it to your work shop and connect it across your DC arc welder. Set the current to 150amps. Put on your safety googles and/or face shield and turn on the welder ac supply. You will witness an immediate acute failure. There will be an instantaneous "pop" and the carbon body will display a hair line crack or pieces of the body spalled off, or it may disentegrate into shards.

Now ask yourself under what conditions can your radio produce the same currents as your DC welder? It is very simple. Your radio has experienced a 6146 tube arc over and it appears more than once in its life time. That arc over produces the kind of instantaneous fault current that will open the resistor. This is where this fuse debate comes from and I wont pick that scab here.

I and others on this forum have shown the math too many times to repeat again in this response. Simple put if you ignore the power supply ESR and just say that the only thing that limits the plate current is 5 ohms then anytime there is accumulation of off gassing inside the glass envelope and that gas ionizes and a arc is established between the anode and the beam forming plates you now have a very low impedance path for 900vdc to the cathode which results in acute failure of the cathode resistors. So for back of envelope calcs we say the resistors see approx 900/5 = 160 amps.

"Why" is an easy question to answer. When you reach for 35 to 40 year old NOS 6146 finals that have been sitting on shelf off gassing and install them in your radio there is always a chance for an arc over event. Some people have good luck replacing the resistors and using the tubes over. Others are not so lucky and have another arc over and blow the resistors again and then you have a few very unlucky people that have to replace their panel meter.

Yes the tubes have a flash getter that should remain active over all these years but lots of theories why not totally effective. Some believe the entrained bubbles of gas come out and cling to the tube element support members and are not diffused inside the envelope where the remaining active barium can easily oxidize them. I dont know why the getter appears to be less than effective. This subject has been discussed at length here as well.

So as you have been told it may be advisable to pull your S2001A tubes from service and replace them with set of 6146B or 6146Ws (I use the JAN Ws from RF Parts and have had very good luck with them. Absent a DC hi-pot you simply have no way to test the vacuum quality of your S2001A other than in your radio. Nothing wrong with that as long as you understand the jeopardy. Also as you have been told I would not raise the wattage rating of the resistors as you are just transferring the fault current stress to the HV filter capacitors, HV rectifiers, and power transformer that rely on the 6a line fuse fault current clearing time.

Tom,

I have no experience with that brand of 6146B so I cannot comment either way.

You might consider reading a few responses on a couple of well known vacuum tube websites selling vacuum tubes, to a question about tubes from China at the following links:

http://www.thetubestore.com/Resources/Matching-and-other-tube-info/Vacuum-Tube-Basics#q6

http://www.vacuumtubes.net/faq.htm#offshore

I have done business with "vacuumtubes.net" and, as I said before numerous times on this group and I'll say it again, I have never received a bad tube from them!!! They stand behind every tube they sell with a warranty, see my last response and their website for their warranty details.

Mike,
It appears that the MFJ tuner you have has an RF sensing circuit.
Right now, I can not think of why the AT-250 is not working. I think that your cable connections are correct. OK...I must ask...does the AT-250 have power? Either 115VAC or 13.6 VDC with the voltage selection switch in the proper position? Do you have any panel light(s) on?...and while keyed in low power...did you push the "tune" button in the upper right corner?
No disrespect intended...I'm just trying to check of stuff in my brain.
I think that the tuner may have an internal fuse.

Thanks, Terry! I am glad you noticed what was missing. I am a retired EE with 44 years of experience andI feel *very *uneasy when I don't know "why" something failed...and you're right, I was getting a lot of advice but very little on the "WHY" end. I don't "think" that I inadvertently caused too much current to flow too long. I only used the the rig for 6 very brief CW contacts before it went and I had quite intentionally kept the power down because I had no idea of the history of the rig. I never tuned up for more than about 150 ma. If I can believe my watt meter, I was pumping out about 50 watts and that seemed to be working very well for me. I can believe thought that despite the fact that the finals "look" pristine they could *easily* have been beaten to death by the previous owner. As it was, he failed to give me the plug for the adapter socket on the back leaving me with a completely dead rig (although it "looked" like it should be working) until I finally figured out that the plug's all important jumper was missing. Once I figured that out, I was off to the races! So, I have ordered some 10 ohm 1W resistors, (metal film to keep the inductance low). I bought 25 (!) *not* because I figure that I will need them, necessarily, but as it was the shipping was near *twice*(!) the cost of the resistors, so why not stock up[?]. I also found a set of new 6146Bs. Hopefully, I be back on the air by Christmas. Tom, K3WFN aka "Carvin' Tom"

Joe,

Thank you SO much for your reply! Don't EVER worry about insulting me....I'm WAY too far down the ladder to be thought of as anything but a Hybrid Newbie! ;-)

Yes, the AT-250 is powered up, with the DC/AC switch in AC, and the power cord plugged in. The meter light is on.

After turning the unit ON via the POWER button, I turn ON the TUNER and TUNE, yet neither light comes on. With the METER set to SWR, and the radio's MODE set to CW or LSB, keying/speaking into the mic shows an SWR of about 4, with no tuner action at all.

At times, typically after the 250 is powered up for a while, the TUNER light comes ON, but I can't seem to identify what happens to cause it to light. When this occurs, turning the TUNE button ON causes the TUNER light to go OFF.

I've taken the top cover off, wiggled the connectors, and assured the CAPS were not stuck. I do not see any internal fuse, and could find none on the schematics.

I've tried all manner of keying the radio in TUNE mode while turning the 250's TUNE and TUNER buttons ON and OFF to no avail.

Clif Holland KA5IPF was kind enough to note "The only thing the AT250 needs to operate with other than a 430 is for Pin 3 on the AT250 cable to be grounded in TX." He adds that "Pin 3 on the AT250 goes to Pin 4 on the remote jack of the 830. The shield on the AT250 end goes to the shield of the plug. The other end goes to Pin 2 on the 830."

I've been tempted manually ground pin #3 on the AT-250, then throw the SEND/REC radio switch to SEND to see if the tuner will run. I guess there's always the chance that the radio's relay, which determines whether a grounded Pin #2 on the radio's REMOTE socket grounds Pin #5 or Pin #4, could be bad.

I wish I could insert .jpg's into these messages to make clear what I'm saying!

Back to you Sir! Mike, N3QIG

Tom:

Yes I like to understand the "why" and some good technical people on here do likewise, but as you know sometimes components just get tired and quit and not always possible to determine the root cause.

With your background you understand without measurement much of what we get (often from very well intentioned folks) falls under category of anecdotal, tribal knowledge, folklore. I usually try to couch my responses in terms of what I know and what I believe. Very important that we can all question one another without getting feelings hurt. Hate to bum dope anyone.

One thing I will tell you is to treat every mod and so called KW hybrid service bulletin with skepticism. This is one area where KW did a very poor job. Make sure it makes sense to you before you embark on performing any and good idea to come here and ask about it. Even the troubleshooting charts in the manuals are pretty much shot-gun/easter egging. If you experience a dead receiver you would certainly not as a first step pull the RF board and replace the RF amp dual gate mosfet!

If you decide to use your S2001A tubes and you pop the new cathode resistors, I would not use those tubes again only because of the potential to destroy your panel meter. I see quite a few rigs come across the bench especially TS820S radios with original S2001A tubes that still have good cathode emission and can hold off 2000vdc to 2500vdc during DC hi-pot testing. I think they were quality tubes. However I do see them from time to time where a hole has been sucked into the glass envelope and an accompanying hole melted in the grey metal anode. It is my belief that those tubes experienced thermal run away (loss of operating bias) and did not have an arc over event.

Have fun

Terry K9TW

Mike,
You can up load various files to the groups home page.You can choose to go to the "photos" area, and over on the right..select 'new album'...entitle your album...ie..."AT-250 to 830S cable connection" or go to the "files" area..look over on the right hand side...select "add folder"...title your folder...and then upload a drawn schematic or something similar. The "files" area does not like .jpg based photos...but may take bitmap. Most files there are text, some with drawings...or CAD generated.
I'm going to try and do some more investigation...this is driving me nuts

Joe,

I uploaded the AT-250 manual to the "files" area. Also created a photo album into which I placed a snippet of the AT-250 manual which shows the pin-out for a cable connecting the AT-250 to non-TS-430 radios. There's also a snippet of the pin-out of the REMOTE socket on the TS-830S.

Any thoughts on my idea of manually grounding pin #3 on the AT-250 ACC socket and try trasmitting to see if the tuner moves?

Thanks! 73, Mike, N3QIG

50389. TS-830S VFO Knob Lock/Tightening?

Mike,
There is not, as far a I know, unless you want to drill into your rigs face plate.
You missed the point of the 'silver ring.' It is for calibrating the analog reading of the silver ring and the analog dial with the digital readout.Look at Pg 21,Section 4.7, of the TS-830S Instruction Manual. Between the 'silver ring' and the junction of the main VFO shaft and the inner analog dial are: silver ring, small flat washer, small spring, small flat washer.

There is one possible way...now that I think about it. You can take a 1.5mm allen type wrench....loosen the main tuning knob set screw...and slide it closer to the face plate..so it rubs against it. But then,...you're gonna hear....scrape....scrape...scrape...when you turn the knob

It seems the VFO knob attracts my fat hand regularly! Is there a way to lock the VFO dial or at least tightening it up? I tried holding the main knob while turning the silver ring to the rear, but no tightening seems to take place.
Thoughts? Mike, N3QIG
P.S. - I know this is cheating, but I did try looking in the manual and searching on the net. ;-)

Mike,
There is not, as far a I know, unless you want to drill into your rigs face plate.
You missed the point of the 'silver ring.' It is for calibrating the analog reading of the silver ring and the analog dial with the digital readout.Look at Pg 21,Section 4.7, of the TS-830S Instruction Manual. Between the 'silver ring' and the junction of the main VFO shaft and the inner analog dial are: silver ring, small flat washer, small spring, small flat washer.

There is one possible way...now that I think about it. You can take a 1.5mm allen type wrench....loosen the main tuning knob set screw...and slide it closer to the face plate..so it rubs against it. But then,...you're gonna hear....scrape....scrape...scrape...when you turn the knob

Good Morning All,
My TS830S was produced prior to WARC band approval. Since I am old enough to come from the breadboard era, are there any tips I should know about locating and snipping diodes D4,D5, and D6 in order to enable transmission on these bands- before I invade my virgin 830?
Many thanks,
Tim, WA3GPU

Topic: 47830 Message: 50393

Tim,
There is no need to snip the diodes, unless you just want to enable 1 or 2 bands.
Take a look at the TS-830S Instruction Manual, Pg 28, Section 6.5.
I find it easier to remove both the top and bottom covers, turn rig upside down...locate the AF Unit...Connector 6, Pin 4...small blue wire. Cut this wire...but leave enough wire length from the connector....and tape up both cut ends. Put on bottom cover...leave top cover off...as you more than likely will need to touch up the associated coils in both RX & TX

Date: 2014-12-05 21:03:19 UTC
From: Mike W5RKL
Topic: 47830 Message: 50394

Tim,

Yes, take the time and thoroughly read the operator's manual before you attempt to operate the TS-830. The answer to your question is in the operator's manual, page27, paragraph 6.5 "TRANSMITTING ON WARC BANDS". You should look to see if the wires or diodes have already been cut before you start snipping anything.

If you do not have the TS-830 operator's manual you can download it from my website

www.w5rkl.com

Click on the Manuals, Docs, and Mods link. When the manual page comes up scroll down to the TS-830 listing and download the TS-830 operator's manual. You should also download the TS-830 service manual while you are at it.

Regardless of your ham radio experience, if you have never operated a Kenwood TS-830 before I recommend you spend time reading/studying the TS-830 operator's manual before you apply power to the transceiver. Learn what each control is for, how to use the controls, what each meter switch position is for (the meter switch positions are active in transmit ONLY, not in receive), how to read the manual, how to read the VFO knob scale, how to check and set the final amplifier's 60ma idling current using the bias pot on the rear panel (must be done before you attempt to transmit!!!), and how to tune the transmitter up using the transmitter tuning procedures outlined in the manual. There are also transmitter tuning procedures on the group's main page in the "FILES" section. Many operator errors can be prevented by spending time reading/studying the operator's manual FIRST before you power up and attempt to operate the TS-830. If you do not understand what the manual is telling you, don't ignore it, ask here so we can help you.

If you do not have a 50 ohm dummy load that has a power rating of at least 300 watts, I recommend you purchase one. MFJ sells a 300 watts dry 50 ohm dummy load, MFJ-260C, for $39. You should use the dummy load whenever you tune the transmitter up. Once the transmitter has been properly tuned then switch to the antenna you intend on using.

Joe,

I loosened the set screw, and push the VFO knob against the radio face. It does scrape a little, but I don't plan on using the radio a lot other than on 40 meter nets, so not an issue.

....now I need to get that tuner working! ;-)

Thanks!!! Mike, N3QIG

50397. Simple repairs

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-06 06:26:15 UTC
From: Lou Blasco
Topic: 50389 Message: 50397

Sometimes a fault may look bad but have a simple solution.

My TS830 was working fine until I turned it on one day and found I
couldn't tune for max power. The best I could get into a dummy load
was around 25W.

OBSERVATIONS:

ALC peaks as normal.
Plate idle current is 60mA.
Plate current at max RF output was around 125mA.
During TX the HV meter reads around 400V.
If I turn off the SG switch and go to TX the HV meter reads around 750V.

ASSESSMENT:

The supply was collapsing under load but it's unlikely to be a tube
as the current is not overly high. The HV supply is a pretty simple
voltage doubler. That is probably the first place to look.

OK, NOW it's time to look inside - careful HV can kill you.

A check with a VOM confirms the HV readings from the top of C24 to ground.
Further testing showed the voltage across C22 collapsed to 0V with TX
and SG switch on.
While you have the hood up it would be smart to confirm D1 to D4 are
ok and other related components are ok - they were.
As everything else was fine it seems most likely that C22 is faulty.
Best to replace both capacitors.

ACTION:

When I bought the radio the seller threw in a replacement HV cap kit
from K4EAA. Hmmmmm? Anyway, replacing both caps brought the HV up to
around 950V no load and around 800V on TX and I have 100W on all bands again.

Remember when working on these radios that HV can kill, work
carefully and watch where to put your fingers, meter probes, screw
drivers etc. Also, MEASURE the HV and make sure it is ZERO before you
stick your fingers inside. Don't trust the bleed resistors to do their job.

Also remember Terry's warning regarding the exposed tops of some
replacement caps. There is around 450 volts on the top (negative) of C24.

An hour on the workbench brought a smile to my face.

Regards

Lou

Lou and others,

The first indication that pointed to the source of the problem was the HV meter indication, in transmit, was only "400VDC". That clearly indicated a failure in one of the HV filter capacitors.

All of the KW Hybrid's HV power supply are "voltage doubler" supplies. When one HV filter capacitor fails, the supply's output voltage decreases by 50% which results in low RF output even at maximum drive.

If you do the simple math, multiply the HV of 400VDC by 125ma, the DC input power is only "50 watts" which would result in about half of that being seen at the output.

My cw side tone is too loud and I want to adjust the volume. Before I go ahead, does somebody know if the adjustment will only change the audio volume of the oscillator or does it also change the drive volume into the vox circuit? Will the vox gain knob reflect the lower setting? If not, how low can it go in terms of heard volume? I would like it pretty light.

I don't know for sure about the other hybrids, but in a TS-530S the CW sidetone volume control (on the bottom of the rig) affects only the amplitude of the audio heard on the rig's speaker. It has no effect on anything else.

What Kenwood hybrid transceiver are you referring to? You have to say what transceiver you are referring to. The following are the CW sidetone level pots that control the sidetone level to the audio amplifier.

The TS-520 series CW sidetone level pot, VR2, on the AF Unit, controls the level of CW sidetone signal applied to the audio amplifier.

The TS-820/820S CW sidetone level pot, VR3, on the AF Unit, controls the level of CW sidetone signal applied to the audio amplifier.

The TS-530 CW sidetone level pot, VR1, on the AF Unit controls the level of CW sidetone signal applied to the audio amplifier.

The TS-830 CW sidetone level pot, VR1, on the AF Unit controls the level of CW sidetone signal applied to the audio amplifier.

Changing the sidetone pot will increase or decrease the level of sidetone heard in the speaker.

Mike's comment about mentioning which hybrid is being talked about is a good idea. Since this group is for all hybrid rigs I'd like to see the radio's model listed first - then whatever the messages is about. e.g., TS-830S No Power Out, TS-520SE No Power Out, etc. Then we don't have to wonder. Just my thoughts. Richard AG5M

Sorry for not saying I have a TS-530s model. I've been here long enough to know better. I was using the phone to post and struggling with the interface took some of my CPU cycles and I forgot to provide all the relevant info. I give my own TAC guys grief for this so I take the feedback as deserved. :-).

I rtfm so I know where to make the change but since it is set where the last owner had it (sounds like 11 to me) I was curious if setting it to a very low audio level would affect the vox gain. Stupid me I now realize I was thinking phone usage for the vox.

Al,

The block diagram on page 29 of the TS-530's operators manual shows the path of the CW side tone oscillator signal through the sidetone level control VR1 and ultimately to the AF Unit's audio amplifier. VR1 side tone signal level has no control over the sideband VOX operation. If you are still unsure simply set the CW sidetone volume control, VR1, to the lowest setting then switch to sideband and test VOX operation into a 50 ohm dummy load. You can always set VR1 to a level that's acceptable to you later on.

As I continue my work on recapping, repairing, and rewiring a TS-520, something occurred to me today.

I found the wiring around capacitors C27 and C28 to be so confusing (compounded by a previous owner having screwed up some of it) that I finally opened up my good TS-520 to look at it. That will also help me figure out where the rest of the wires going to the rectifier board should go. I am lucky I had another set to take a look at; you can study the schematic and figure it all out, eventually, but a proper example helps even more than I thought it would.

It occurred to me then that a useful addition to the Group files would be clear, close up photos of the insides of original, unmodified and known functional transceivers to serve as a reference. I am willing to get started on this effort if the Group thinks it worthwhile.

Date: 2014-12-08 01:53:48 UTC
From: Mark Gilger
Topic: 50407 Message: 50407

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by Jimmy, WB2KNR. There were 25 stations checking in under good band conditions. There were 3 new check-ins: W3DBL, KB3VS, and KD8VME.

We had the following number of radios checking in.

5 running TS-520(x)
4 running TS-530(x)
4 running TS-820(x)
5 running TS-830S
0 running TS-511
0 running TS-511
0 running 599 twins

I was running my Drake 'C' line & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were 21 stations checking in under fair band conditions. There were 5 new check-ins: WB1AJX, KF4OJA, K0HZL, N4JK, and VE3DWI. He had the following number of radios checking in.

4 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday□s net total 142, Sunday□s total = 88

December 2014, Saturday□s net total 20, Sunday□s total = 21 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Hi everyone,
I got my TS-520S back on the air this weekend. I have been inactive for 30 years and it has been sitting all that time. I bought it new in Dec. 1979 from Hoosier Electronics in IN. I paid $580 according to my logbook, a lot at the time for a college student!
I cleaned up the bandswitch contacts, cleaned the variable cap wipers including the VFO, replaced some of the electrolytic caps, adjusted the DC voltages, and touched up the alignment. It still has the original driver and final tubes. I get good ALC indication and it is loading up well.
I was on the air on 80, 40, and 20 and it is working great. I also made a CW contact today on 20M, it bit tough copying but I managed. I enjoyed using a straight key in the past and it was good to do this again.

73,
Howard WB1AJX

Howard,
That's and excellent story. Not many will keep a rig like that sitting around...but now you know the dividend!. Keep a watch on your HV caps to make sure they are not leaking...which could lead to a catastrophic event if one or both fail.
This group, with the assistance of wb4hfn, has a data base regarding the KW hybrids. Contact Ron...via wb4hfn "dot" com and give him the info...model, serial #, date purchased, and from where (if known), to be preserved for posterity.

From: Rory
Topic: 50412 Message: 50412

So why did the 830S drop the RTTY function? Looks like I want the 820S if I want to do RTTY FSK.

Thanks

Rory

I have no idea why Kenwood didn't include FSK as a mode in the TS-830S.

The TS-820's "FSK" mode actually shifts the RF carrier based on the jumper settings outlined in the 820 operator's manual (170Hz or 850Hz).

You can operate RTTY using the TS-830, all you need is a sound card interface and your computer running free RTTY software you can find on the web. Many RTTY operators operate VOX, keeps the number of connections between the computer, sound card, and transceiver to a minimum.

Typical power output using RTTY is between 25 and 35 watts. Keep transmit times short and keep the MIC gain set to a level where no ALC is indicated.

I operated RTTY using a Kenwood TS-520SE for years using a "Flesher TU-170" and a Model 28 KSR.

I use my TS-830S with a SignaLink USB interface and the simple and free MMTTY software for enjoyable AFSK RTTY. For "pure" FSK RTTY, it's my TS-940S at work. It is curious, however, that Kenwood omitted an FSK mode from the 830 then resumed it in later models. In on-air practice, however, I don't find any real difference between AFSK and FSK RTTY. Maybe the guy on the other end does, but nobody's ever uttered a critical word.

50415. Listening to your own transmission

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-09 06:25:50 UTC
From: Lou Blasco
Topic: 50412 Message: 50415

Hi All,

Sometimes it would be nice to listen to your transmitter output to make sure everything is ok before you get on the air. I don't know about you but I find it difficult to assess my own voice in a set of headphones or listen to my transmission off air through another radio. Asking for on air reports is a bit of a lottery, and I've heard excellent reports given for what were clearly terrible transmissions.

There has to be a better way.

Then it occurred to me that I had the perfect audio source on hand to feed into my radio. Not too far from home I have a number of 50kW MW radio stations that have really good balanced audio, no compression, no music, just talking and both male & female voices depending on programming. Because the transmitters are so powerful the audio is clear and noise free. I made up my own version of the W2IHY iBox http://www.w2ihy.com/ibox-kit.html (the manual is right there for downloading) and connected my MW radio to the input of my transmitter.

Now I can run my transmitter into a dummy load at full power and listen to the result on another receiver. There's usually enough leakage from the dummy load to make a really big signal in the shack. Depending on the TX power and the amount of leakage it may be necessary to use only a short piece of wire in the antenna socket of the receiver.

Now I have an easy way to check my transmitters without having to rely on the opinion of others.

Warning 1: Don't transmit into an antenna when you do this as you will surely be breaking the law by re-broadcasting commercial content.

Warning 2: Your Kenwood is not a broadcast transmitter - don't leave it in TX all afternoon so you can listen to the ball game on HF.

Interesting experiment 1:

Using a PEP wattmeter adjust your mic gain until you're hitting 100W on voice peaks. What is your ALC meter reading?

Interesting experiment 2:

Don't touch those dials, just switch your wattmeter to average reading. What does the wattmeter read now?

Interesting experiment 3:

Go to the receiver and tune either side of your transmission and make a note of where you can no longer hear your signal. Now crank up the mic gain and watch your ALC meter and listen for the increase in noise either side of your transmission. Does this explain why your mic gain and ALC meter are so important? Can you hear any difference in your transmission when the ALC is full scale?

Obviously this is only for testing purposes and you shouldn't run your transmitter for hours in this configuration. I'm sure I'm not the first one to think of this but I think it makes testing transmitters easy and fun.

Regards

Lou

If you had a Kenwood SM-220 you could use the TWO TONE generator to test you transmitter. This is the way you check linearity!

Lou and others,

I'm sorry but I do not support this recommended method of testing. There are too many inexperienced hams/members on this group that could easily make a mistake and end up violating FCC part 97.

Vast majority of people (including me for my customers) spend time adjusting VFO knob clearance so it does not produce any drag/rubs from lock to lock, they purchase expensive weighted flywheel knobs, they apply PTFE based lubricants to the gear train all in an effort to produce quiet and silky smooth operation.

I even once had a rig come across the bench where fellow bored a hole in front panel and mounted a small belt drive crank to slow down the tuning rate on his TS-830. A real butcher job.

What an interesting world!

I'm rebuilding some Yaesu FT901/FT902 radios and the factory applied grease to all the front panel knobs and now that grease is like a glue. You can hardly turn any knob now.
So they all need to be cleaned or treated with a Deoxit chemical. The planetary drives for the plate tuning & preselect all have to be disassembled and cleaned in lacquer thinner and relubed.

You have no way of knowning if it is factory lubricant or not. Most likely it is but cant tell for sure.

After cleaning try lubing with very small amount of Tri-Flow applied with an artist brush or Magna Lube G. Doesnt require very much.

I find that the "Jackson" reduction drives on the KW hybrids Tank capacitor are commonly stiff. Have to remove them and remove the small ball bearings and spring and remove all the hardened grease of the balls and races. I reassemble using Magna lube. Kind of a tedious task but usually get good results.

Terry,
All three Yaesu FTs have frozen knobs from a solidified grease, so statistically speaking, I would conclude its a factory applied lube (and its causing some green corrosion on all the brass)
Were did you get the Tri-Flow lube from a bike shop? I remember using a chain lube of the same name 10-20 years ago.
I'm using various lubes from MCM Electronics, including the Deoxit product line.

Thanks for the previous advice on using thin lube on my Ts-830 VFO shaft. There was a build-up that was binding the shaft.
* Was able to obtain a tube of
GC Electronics Reach-All Pen OIler, #10-985 , from Jameco.
* Applying partial drop and waiting and slowing working shaft,

repeated several times , loosened the shaft.
* The Kenwood works smoothly now.

* This rig is a Cadillac
... glad to have the Kenwood and this group for advice.
Glen Ellis, KK4LPG

Glen

Wouldnt it have been nice to have been able to buy a new TS-830S along with all the matching accessories. A pretty big hit on the family budget back then.

There was a time when it was a contesters favorite and in full filter config a CW ops favorite. It can still hold its own today.

Like all the hybrids it has some unique issues that presents some challenges as it ages and is passed thru lots of hands.

Best of all worlds is to own or have owned all of the KW hybrids at one time or another. Many of us buy and sell regularly and in my case almost always regret selling! I have two full filtered gold emblem 830s and no plans anytime soon to sell. Unless I could upgrade to a pristine 6 or 7 million series one.

Enjoy your "cadillac".

50437. TS830S marker problem

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-11 20:32:49 UTC
From: Jim Showker
Topic: 50325 Message: 50437

Hi all,
Haven't been truly stumped for a while, but have a marker problem that will not relent.

The marker gives strong 100khz markers but 18khz or so markers in between with /lots/ of birdies and noise. I have replaced all three transistors in the marker gen on the PLL board, and the D1 switching diode on the RF board. It was intermittent, then seemed to be fixed after one of the components I changed, then showed up again, and now is full time. I have checked every component in and around the circuit, all seem to be good. The 100 khz signal from the PLL is good.

This problem showed up once before in another 830S, just one or two times, and then went solidly good. Never appeared again, so I didn't figure out then what was wrong either.

Thanks for any ideas.
Jim

Jim,

Sounds very much like dry joint or component that as it heats up goes out of specs, had one on a 830s some years back, ended up being the molex connector. Have you tried high magnification and good light source, would typically look at the molex pins\tracks and then around the marker component section.

The TS-830 RF Board schematic calls out the Marker "block diode" D1 as a 1S1527. This is wrong. It is a 1S1587 which is an ultra fast switching diode. If you used an NTE-177 that is not a good sub. I would try a NTE-519 or a 1N4148.

If D1 is shorted you will have many birdies across the VFO range with most prominent at 1.9mhz. Birdies will be present approx every 18khz with the Marker turned off. Rig on dummy load.

Unplug Conn 3 Pin 2 on RF board and read the cathode of D1. Should be approx 1.7meg to chassis grd.

With the Marker ON Conn 3 Pin 2 should read 1.8vdc and MS should read "0" vdc. With Marker OFF Conn 3 Pin 2 and MS should read 8.9vdc (Conn 8 Pin 3 on PLL board).

With shorted or leaky block diode will read approx 6.9 to 7.2vdc at MS and Conn 3 Pin 2.

I would try another block diode. Never seen Q30, 31, 32 bad.

I just use a stick of wood cut to the the thickness I need, and shim any gear that I want. I guess 'extension feet' might be all nice and pretty, not a thing wrong with 'pretty,' but a scrap of wood works just fine for me.... Consider it for the interim perhaps, until you locate what you prefer??

Go to a hardware store. Find some rubber feet that will do the job. In the unlikely event you cannot find any that are tall enough, then stack two atop one another, like Heathkit did.

Some friends gave me a circulating fan that stood on a pedestal some years ago. Unfortunately the pedestal met my car's front wheel. I threw away the pedestal, but noted that the rubber feet for it were just what you need to raise the front of a radio and salvaged them.

So, look around and I think you'll find something suitable, possibly in unlikely places.

Good Luck!

I am puzzling over something on the TS-520 I am rewiring/recapping.

On my working TS-520 there is a white wire that goes from the X-43-1090-00 rectifier board forward to the front of the radio. Apparently it turns and goes up, just behind the front panel. I have not traced it further that that yet.

Oddly enough, the TS-520 I am repairing has no sign of that white wire. It does not appear to be there at all. Now, all the wires coming "out" of the board to the rest of the set were cut and I am reattaching them one by one as I verify them. But in no other case was a wire removed entirely.

Any ideas out there?

Thanks,

Robert

It sounds like you are describing -C (bias voltage) and if so it goes to the RF board and eventually to the bias voltage adjust pot and to control grids of the finals.

White is normal color convention for -C supply. However never bet your life on color conventions.

One point of clarification. When I say white is the "normal" convention I am talking about the three 520 series radios. -C is typically purple on 820s and Wht/Blue on the 530/830s, but again dont bet on any color conventions ie Red is always + and Black is always -. If cant trace lead in the harness then try ringing it out. May have to lift it and measure or see what is lost. Not as easy to do with wire wrap terminal posts.

Teryy:

Yes, I only saw one white wire on the rectifier board on the working TS-520, although. I am having trouble relating it to the data from the manual (I did not write notes on the expanded schematic and foil layout), I think the -C post is indeed the one with the white wire. Now what happened to that wire on the other TS-520? I guess I'll figure out where it goes on the RF board and then trace it back the other way.

I gather then, that you know of no mod that got rid of the white wire? After all, that function is still required.

Reminds me of the time my Toyota quit running. I made some measurements, looked at the schematic, and it became obvious at once that a fusible link had blown. I found that fusible link, next to the battery, right away, And it was hooked to .... nothing. The wire that was the problem area was not there. Now, I had driven the car for about 18 years at that point so I was fairly sure that it had run at one time. I finally decided to heck with that mystery; I would just run the wire per the schematic myself. In the process I found that real problem, - a bad connector - and the fact that they had done a mod that ran the wire to the alternator rather than to the battery.

As for color codes, I recall one F-111 item where they wires were yellow and green. I don't recall which was positive and which was negative, but on a later version of the part they made them black and red. And black was positive and red negative!

Thanks!

Robert

When my screen voltage failed in my
TS520, tracing the wiring around the radio from the rectifier /resistor board to the switch on the back and to the final section, required me to cut some cable ties and spread out the bundles to follow some of the wires. Seems like most of the wires are identical colors. My radio is Ham Radio...CW is Real Radio

Subject: [TS-520_820_530_830] Missing Wire on a TS-520

I am puzzling over something on the TS-520 I am rewiring/recapping.

On my working TS-520 there is a white wire that goes from the X-43-1090-00 rectifier board forward to the front of the radio. Apparently it turns and goes up, just behind the front panel. I have not traced it further that that yet.

Oddly enough, the TS-520 I am repairing has no sign of that white wire. It does not appear to be there at all. Now, all the wires coming "out" of the board to the rest of the set were cut and I am reattaching them one by one as I verify them. But in no other case was a wire removed entirely.

Any ideas out there?

Thanks,

Robert

Well just have to remember that schematic and wiring diagram are two very different things and of course in the electrical power world it is a must to have both. Would be nice to have them for our radios, but I dont know of any radio mfg that routinely provided them. Common to get a table of abbreviations and maybe a table showing each end connection.

Not understanding the as built configuration has gotten people killed. That along with not using proper PPE and taking a contact voltage test before barehand touching.

In the power world the schematic is called an "elementary" and like the schematic you use it to see how the circuit works but it tells you nothing of the actual as built wiring.

There are conventions for drawing schematics and elementaries, but KW didnt necessarily adhere to what we used in the states. Probably drives EE hams nuts especially those who went on to RF communications design careers.

I cant imagine someone changing out the -C wire from the HV rect board to the RF board. -C lead sees virtually no current so should not burn up, but it can be hurt if have an arc over from anode to FG lead. Fortunately this doesnt happen too often.

Here is another idea:

Reasonably well stocked hardware stores have rubber stoppers in various different sizes and lengths. A couple of those shpuld do the job and you probably will be able to find a larger array of potential candidates than you will by looking for rubber feet.

Good Luck!

Robert

Well, we now have one mystery cleared up but another one of even greater magnitude discovered in the process.

I found the "missing" White wire. I had identified it as a Tan wire, because it got smoke stained by the effluents that accompanied the catastrophic failure of the rectifier board.

Now the question is, "Where is the Tan wire?" for the good TS-520, there is Tan wire that comes from the front of the radio along a different path than the White wire and connects to the STB post on the rectifier board.

The only Tan wire that travels along that much the same path in the TS-520 undergoing repair does not go to the rectifier board at all but instead goes to a terminal on the bottom of the power amp section. I do not see another Tan wire. I doubt very much that this is a mod; it sure looks original and factory in nature

AND - on my copy of the foil image and the schematic, there is no STB post on the rectifier board in any case. I will have to see where it would fit in the schematic. The TS-520S rectifier board does have an STB post. Maybe there was a "TS-520 and 1/2 S" that had an STB post on X43-1090-00 board.

I'll dig out the old rectifier board I replaced and see if it has an STB post. And I'll have to do some more looking at the wiring of both the good radio and the smoked one.

And yes, I sure wish we had a wiring diagram to complement the schematic. When I am doing something like working to de-modify a BC-348 the wiring diagram probably is of more value than the schematic, anyway.

We'll have to put some good wiring diagrams in those new versions of the TS-520 and TS-820 manuals we are going to write some day...

Thanks!

Robert

Yes, I am having to do that as well - except that this set does not have real cable ties but rather those twist ties like you used to secure bread bags. I don't think the modern cable tie had been invented back then. I guess when I get it all fixed I'll install real cable ties.

Funny thing occurred a few years back. I had taken my Mom Christmas shopping and a lady backed her Toyota out of a parking spot to the accompanyment of horrendous scraping noises. The undersides plastic faiings had not been properly secure and came loose. I had s sudden inspiration and dashed into a nearby Radio Shack where I purchased a bag of cable ties. With the cable ties we were able to secure the fairings quite well.

I marked down in my mental notebook to be sure and keep some cable ties in every car's emergency repair supplies.

And as a result of doing that good deed, I got a $10 off $40 purchase coupon from Radio Shack, which I used to purchase a Grundig G6 receiver on sale at an even cheaper price.

Robert,

If you compare the TS-520 and the TS-520S Rectifier Unit boards, the "STB" in the TS-520 is the "210A". Kenwood made a new terminal, STB, on the TS-520S and TS-520SE to provide the CW side tone "STB"voltage from a resistive voltage divider consisting of two 100K ohm resistors in series to ground off the 210A supply. If you follow the TS-520 "210A" terminal wire you will see not only does it go to the RF unit but also to the AF Unit's "STB" terminal. The TS-520S and TS-520SE "STB" terminal wire goes to the AF Unit's STB terminal.

No Carl, there actually is a TS-520X.

Here's are a few pictures of some Kenwood TS-520X transceivers.

The above pictures of the TS-520X were cut and pasted from different Japanese websites using "Kenwood TS-520X" as the search phrase. I do not have a manual for a TS-520X so I can't say what the normal DC power input would be. However, if the TS-520X has a single S2001A (Japanese equivalent of the 6146B) in the final then that would explain why the power output is low.

Kenwood made a TS-530D that had a single S2001A (Japanese equivalent to the 6146B) final tube that produced low power output. The "D" model was for the Korean market only.

The TS-530SP had a "Notch Filter" but the plain TS-530S did not.

The TS-830M has the "AM" mode but the TS-830S does not.

Here's one for ya, a Kenwood TS-520V. The TS-520V is a 100 watt transceiver, same as the TS-520/520S/520SE. The "V" model appearance appears to be equivalent to the U.S. Kenwood TS-520S model. Notice the white "Heater" switch in the same spot and the color scheme is the same as the TS-520S.

STB on a straight TS520 is fed by a voltage divider R16/R17 100k ohm. They are mounted on a phenolic terminal strip near the front 6146 tube sockets and fed via 210A. STB is not fed directly from the Rect Board.

Unlike the White -C lead wire I dont have the STB wire colors firmly committed to memory, but seem to recall yellow and brown perhaps. STB by the way is side tone bias supply as it is used to forward bias diode D3 in the side tone phase shift oscillator RC network. This opens and closes the regenerative feedback path to ensure no sidetone oscillator leakage.

I am pretty sure that STB and R16 and R17 have been covered here before, but may not be easy to search on?

You might want to contact Jimmy WB2KNR who has 9 or 10 TS520 rigs and usually has covers off one or more working on them.

Robert,

A little further explanation about the difference in the 210A and STB wiring from the Rectifier Units in the different TS-520 models.

If you look closely at the TS-520 schematic wiring starting from the Rectifier Unit's "210A" terminal, the wiring path goes up and then a wire crosses to the left and turns back down. The wiring path then continues down and then turns left and continues to R16 and R17 (both 100K 1/2 watt) resistive voltage divider network. The wiring continues on from the junction of R16 and R17, to and terminates at the AF Unit's "STB" terminal.

What Kenwood did was to move R16 and R17, again both 100K 1/2 watt resistor, onto the Rectifier Unit and relabeled the 2 voltage divider resistors as R9 and R10. R9 and R10 is the same 200K voltage divider network but is now physically mounted on the Rectifier Unit with the added "STB" terminal in the TS-520S and TS-520SE models.

Other than those wiring changes and additions to the Rectifier Units, the TS-520 210A and TS-520S/TS-520SE STB wiring from the Rectifier Unit to the AF Unit's STB terminal is the same.

Mike

No problem. Never know who is typing at any given time.

You are good at teaching how to read schematics and I bring the actual as-built config to the table so both add value. I am very familiar with physical construction of most of these KW hybrid circuits having had to troubleshoot just about any problem that can commonly occur with them. Just as you are I suspect with Heath and Drake rigs physical layout.

This subject covered previously but I guess easier for all of us to just respond again.

Sometimes my memory is flawed or stuff is filed too far back in the "file cabinet" for me to pull it out. I never mind a correction or any amplification. In fact amplification can be a good thing!

Mike:

One thing I eventually wanted to get around to was asking about the differences between the TS-520 and TS-520S rectifier boards. I printed out enlarged copies of both the -00 and the -02 boards because for some reason I was under the impression that I had a spare board that was a -02.

So you and Terry got there ahead of me. Thanks!

Now, again looking at the broken TS-520 this morning, I find no evidence of the "missing" tan wire ever being there in the first place. Looking at the original, fried and unrepaired, X43-1090-00 rectifier board removed from the broken TS-520 shows that it does indeed have a STB post - and which shows no little or no evidence of ever having anything attached to it.

But looking at the broken TS-520 and the good one, I see circuit differences in the final amp section. These were not wrought by some guy with some wire cutters and a soldering iron. Clearly, there were production differences between the broken TS-520, Serial No. 230685, and the working one, Serial No. 311080.

So, my task of repairing the TS-520 has become a lot more complex than just making sure the wires with the same color codes go to the same places. I am going to give this some more examination.

Thanks again to Mike and Terry!

How do you know if it is a production model difference or if someone has inappropriately swapped out boards? One way would be if you still had factory wire wraps on the terminal posts.

There are numerous differences between the 520 and 520S that have to be evaluated before swapping boards.

50476. Post on my Website

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-13 15:54:10 UTC
From: wagstw46@...
Topic: 50476 Message: 50476

Recently got couple of off reflector questions. One on the What and Why for resting plate current adjustment and the other for running RX Level Diagrams. I have discussed both here in the past.

See my website http://www.k9tw.com http://www.k9tw.com for white papers on both subjects. One is under FAQ and other is under How To Guide.

Also, I have seen a large influx in TS820S repairs in last several months and have now had 3 rigs with bad xtal filters (filters getting hard to find and expensive and never know if any good despite the seller saying in good condition). Have had one bad CW and two bad SSB filters. Bad ranges from Fc shifted to non-symmetrical response curve. I have posted a sweep of one of the bad SSB filters under the Picture/video tab on my site. I cant tell you how nice it is to now have a decent Spectrum Analyzer. Should have cut back on kids birthday and xmas gifts a long time ago. Just kidding! Got by Ok with Sweep gen and O-scope for many years.

As with all my white papers I have no one to QC them prior to posting so if you see errors especially in technical accuracy please contact me off the reflector to discuss.

Terry K9TW

50477. Brand New TS-820s and 820 VFO. Whats it worth??

Yahoo group: TS-520_820_530_830 (2014)

Topic: 50477 Message: 50477

Years ago, I purchased a brand new (never been put on the air) 820s and matching VFO in original box's with paperwork. They have been in my basement for at least 20 years.

Been wondering what they might be worth.

Terry:

There are indeed factory wire wraps on the fried X43-1090-00 rectifier board I removed from the broken TS-520. Of course someone had cut the board's output wires and spiced in some wire, I assume for purposes of troubleshooting. I found the 33MFD 160V caps on the board to be bad, so that troubleshooting approach would not have taken that into account.

Aside from that, the wiring differences between the working TS-520 and the broken one involve areas other than the rectifier board - the power amp section. One TS-520 has a two terminal strip in that section, with only one terminal of it in use. The other one has a 4 terminal strip in use, with at least 3 terminals used.

By the way, the broken TS-520's "TS-520" nameplate below the main tuning knob has been replaced by one that says "TS-520S" but based on its internals, features, and nameplate/Serial No sticker on the back it is a TS-520, not an S.

Robert,

The "X" number on the component side of the board does not always reflect the correct version of the board. I have seen what appeared to be 2 identical board with the same component side "X" number but the foil side numbers were different! You have to turn the board over and look at the foil side. You can see what I am talking about by looking at the TS-520 Rectifier Unit's Xray view, foil side number page 35. The foil side number shown is "J25-0936-04" which not the same as the component side number "X43-1090-00".

I had a TS-820 a number of years ago. I replaced the AF AVR Unit board. The replacement board fit perfectly, plugs fit fine, it looked the same, BUT after installing the replacement board and the 820 was powered up, there was no receive audio. I could see the S meter bouncing around but I couldn't hear any audio. I checked the component side number and it was the same as the old board BUT when I compared the foil side numbers, they were different. I mentioned this to the seller and he sent me another AF AVR Unit board that had the same foil side number and all was well.

It's quite possible you can replace the Rectifier Unit board with a different "foil side" numbered board and it will work. However, if it does not then you have to look at the foil side number to ensure it's the same as the board it replaced.

It cant be a J25-0936-04 if it has a STB post on it.

Look at the Generator board and see if it has a reed relay on it. Black cylindrical component on board edge near the HV filter caps. Most commonly will be an Omron relay. If no reed relay then it is a 520S and not a 520 or Dr. Frankenstein has been at work!

Trevor,
Pg 3 of the TS-820S Operating Manual states the specifications.
   with 120/220VAC: 200 watts PEP for SSB operation 160 watts DC for CW operation 100 watts for FSK operation.
   operation on 13.6VDC(nominal) the inputs are: 120 watts(SSB)
90
(CW)
60 (FSK)
If you are new to these type of rigs, I suggest that you obtain theOperating Manual and read it, so you have a basic understand of how to properly tune it up and operate it. It's not that hard..just takes a bit of practice.

I mean no disrespect but questions such as this one can be answered by referring to the operator's manual first. If you do not have the operator's manual, you can download it from my website

www.w5rkl.com

Click on the Manual, Mods, Docs link at the top of the home page. When the page comes up scroll down to the TS-820 listing and download the operator's manual.

Mike:

I noted the notation on the foil side and was about to ask if that can be used to differentiate between then different versions of the rectifier board, but then decided we already had enough to discuss.

The foil side notation on the board removed from the broken TS-520 is J25-0936-24. By the way it looks to be in good shape except for the bad caps and expired resistor and appears to be easily rebuildable.

Looking at the broken one again, it has a Five terminal strip mounted down by the power output section, with all five of the lugs (counting the center grounded one that is also the mount) in use. The good TS-520, which has a later serial number, has a Two terminal strip, with only one lug in use in that same location.

Thanks,

Robert

Terry:

The old failed rectifier board out of the broken TS-520 says J25-0936-24 on the foil side.

I'll take a look for that relay, but I think it's a TS-520. Anyone have a serial number versus model number list?

.I suspect that as new models were introduced that changes in older models were made in order to accommodate the later circuit boards and thus improve commonality

Thanks,

Robert

OK some how I thought you said it was an 04 board with a STB post. A 24 board is the 2nd revision to the board. I do not know what changes were made.

Unfortunately I dont know of any KW documentation that will tell you what changes were made from 04 to 14 and from 14 to the 24 board.

For example the latest IF board I have seen on the TS-820S is a 53 series. See lots of 33 boards and a few 43 boards and as Mike says best to use same foil side serial number board. I have been able to install any of the revised IF boards in the TS820, but that is not always the case. With visual inspection it isnt always obvious what was changed.

non taken Mike... Here is my concern I tune the radio up just as it is described in my manual. I see 200 on the radio's meter when in the switch is in the RF position. But on my external SWR/ power meters (I tried two different units) are only showing a PEP of 100 watts. I am in USB and generating a carrier tone (via my PC) and it peaks and holds at 100 on my external power meters.. SWR is a 1.2:1 any ideas?

The RF position on the rig’s meter shows relative power. The actual value (200 in your case) means nothing other than it is more power than a reading of 199 and less power than a reading of 201.

The reading on your wattmeter is what is important. About 100 watts PEP is typical for the Kenwood hybrid rigs.

Trevor,

The KW hybrids, as many ham transmitters, have power levels expressed in PEP and CW carrier.

CW carrier power is typically referred to as "DC Input" power which is the maximum carrier power the final amplifier is capable of producing. A watt meter is not required to determine the DC input power. All that is needed is to note the final amplifier's high voltage and cathode current at maximum RF output carrier. For example, if the transmitter is properly tuned, resulting in a high voltage indication of 750VDC and cathode current of 225ma, the DC input power is approximately 168.75 watts (750 x .225 = 168.75).

Output power is the ratio percentage of input power verses output power. One can easily determine the approximately output power using the following formula

Pout = Pin x .6

Therefore, in the above example, the typical output power will be approximately

168.75 x .6 = 101,25 watts

This is CW carrier power NOT sideband power.

PEP power is the instantaneous peak envelope power of the undistorted RF sine wave cycle. PEP power cannot be measured by the same method as DC input power can. A peak reading watt meter is required. Most watt meters in ham stations today are of the average power variety. Peak reading watt meter have a peak sampling circuit that requires DC power to operate. Don't be fooled into believing your watt meter is a PEP watt meter simply because it requires 12VDC. There are watt meter that have 12 volt lamps to light the meter and that 12 volts is not to power a PEP circuit in the watt meter. Unless the manual states the meter is a PEP meter, it's an average watt meter.

The typical sideband power output displayed on an average watt meter with the MIC gain set properly (ALC peak indication is no higher than the top of the ALC scale), is between 25 and 30 watts on peaks. This low power level typically confuses hams today into believing there's a problem with the transmitter. After all the manual says the transmitter is a 200 watt sideband transmitter so I should see higher power so up goes the MIC gain so the watt meter displays peaks on the order of 70 to 80 watts. The operator now thinks everything is good. What the operator does not realize is, he/she is now splattering up and down the band with

a distorted signal, making a lot of enemies and causing intentional interference to other stations outside of the normal 3Khz wide sideband band width.

The input power – DC – to the final stage should be about 200 Watts PEP.

The output amplifier runs at somewhere around 50% efficiency.

The RF output power should be in the neighborhood of 100 Watts PEP.

I incorrect stated:

"Output power is the ratio percentage of input power verses output power."

That statement refers to the amplifier's "efficiency" percentage. The amplifiers efficiency percentage can be found using the formula:

Ampeff = Pout / Pin

Where

Ampeff is the percentage of output power verses input power
Pout is the output power
Pin is the input power

An example is an amplifier that produces 170 watts DC input power and produces 101 watts output, the amplifier's efficiency percentage is:

101 / 170 = ,59

That's the typical maximum amplifier efficiency for a final amplifier operating in Class AB1. The KW hybrid final amplifiers operate in Class AB1.

Power output will be less due to losses in the amplifier and the PI Network.

This subject has brought up exactly why I modified the finals in my 820s. The old QST article on installing the WARC bands which I used as the basis for my conversion pointed out that the finals only ran at 50%. It also means that the Kenwood Hybrids can be very tough on the finals. The power has to go somewhere and it can simply be in plate and screen dissappation and heat. I modified the tank circuit inductance and got the finals running at nearly 60% efficiency. This makes it a LOT easier on my 6146B's that I use. I've also replaced the old "tin" fan with a 12 volt modern computer type. Less power used but a lot more airflow. The case over the finals is also modified with perforated metal sheet to let the heat escape more easily. After all a final of this type has a theoretical 68% efficiency rating. My old home brew TT21 final actually got to 67% on 14 MHz, so getting near the optimum is not impossible. Of course the very small amount of space in a hybrid is a limitation, but measured results still leave me of the opinion that Kenwood did not take enough care in the final tank design. Trevor,

The front panel "RF" switch position on the KW hybrid is NOT a watt meter!! The RF meter displays "relative" power. The RF switch position circuit samples the RF and rectifies the RF by a diode. The rectifier RF is now a DC voltage that is applied to a voltage divider consisting of fixed resistors and a pot. The pot is found on the rear panel labeled "RF VOLT". This pot is adjust to display a 3/4 scale indication when the transmitter has been tuned for max output power in CW mode. Again, the RF meter switch position is not a watt meter, only "relative power" is displayed.

There will be inherent losses in the final amplifier that will result in lower power output when compared to the inputpower. The typical loss percentage is approximately 40%. This is normal for the amplifier operating in Class AB1. As I said the KW hybrid final amplifiers operate in Class AB1. The amplifier efficiency can vary between 55% and 60% but the maximum efficiency is approximately 60% which is determined by

Ampeff% = Pout / Pin

Pout is the power output
Pin is the power input
Ampeff% is Amplifier Efficiency

If you tune the transmitter up into a 50 ohm dummy load and see approximately 170 watts input (HV x IP = DC input power) and 100 watts output then the amplifier is operating properly and the final amplifier's efficiency is:

100 / 170 = .58

or 58% efficiency in the final amplifier of power out verses power in.

The typical sideband power output as indicated on an average watt meter with the mic gain set properly and peak ALC indications on voice peaks of no higher than the top end of the ALC scale, will be between 20 and 30 watts. Too many hams see this lower power output in sideband and think something's wrong or they have made an adjustment mistake so they turn the MIC gain up and see higher power displayed on their average watt meter. What they do not realize is they are now producing boat loads of splatter up and down the band causing intentional interference with other stations on the band. They ask their buddies how they sound and the answer quite often is,

"you sound great"

when in reality they may sound LOUD at the distant end but they are splattering up and down the band causing all kinds of interference to other stations.

In short, you do not have anything to be concerned about. Just make sure you properly tune the transmitter and set the MIC gain for the proper ALC indication on voice peaks.

From: Mike W5RKL
Topic: 66 Message: 50499

I forgot the comment on a few additional topics.

Every ham station should have a 50 ohm dummy load, whether wet or dry. The transmitter should always be tuned up into the dummy load first. The KW hybrid transmitter tuning procedure can be found in the hybrid's operator's manual. If you do not have a 50 ohm dummy load, there are plenty of them being sold on eBay or you can buy one from various outlets on the web. A simple 300 watt dummy load (dry, no oily mess) is the MFJ-260C which has a maximum power rating of 300 watts. The 260C has a 100 watt carrier rating of 90 seconds (see the manual for details on carrier power ratings). The 260C's approximate cost varies between $35 and $40 plus shipping. I have one I use on the bench with all my 100 watt output exciters (transmitters).

Quite often hams, when adjusting the LOAD control for maximum output indication on the hybrid's relative RF meter or their watt meters, will, after achieving a peak output indication, go back and readjust the plate for a further dip in IP current. Do NOT do that!!!! Once the Plate control has been adjusted for a dip in IP current and the LOAD control has been adjusted for maximum RF meter or watt meter indication, STOP adjusting!!! Set the meter switch to IP and if the IP indication is higher than 225ma, reduce the CAR control (rotated CCW) so the IP meter is at 225ma. The transmitter is now properly tuned and you can switch to the antenna or tuner input, which ever one you chose.

50500. RL-1 repair.....on Ts 830s

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-14 18:34:47 UTC
From: Mike McHugh
Topic: 50500 Message: 50500

Hi folks. Though you would like to hear of my RL-1 replacement..... This condition did not manifest over a period of time...I went to use my 830 after quite a while since last use..... I got NOTHING on meter while attempting to "tune" up.. NOTHING!!!! No HV , nothing... (Receiver worked fine).
Ok, off the operating station and over to the "shop" for the rig.... On the way off the operating position I forgot to unhook the hand mic from the holder....
More on that in minute..First thing ,after unbuttoning,was listen for the sound of the relays clicking on "send" switch actuation.... I did hear one relay. The TR relay but the one on the AF-AVR unit just sat there.... NO actuation..I did manually actuate (quickly) and got the HV read on meter..... Ok, guess I better go for the replacement of said relay..... Now, where, the heck, did I stow that part??????? After half hour I found it right under the operating station, In back of a drawer. Geez!ok, on to the repair.... Not easy... The leads to the replacement relay just ,barely, came through the foil side of board... One of the pads popped off while soldering so had to use two strands of 24 gauge stranded wire to "splint" the pin to a good part of the copper run... Whew, Got that done.... Back to the operating position..... Ooooops now for the mic cord repair..Ok got THAT done, Duh!My point to my story is that the RL-1 failed at the coil... Not dirty contacts within the relay.... The coil just would not actuate...It was the original relay and Guess this was just one of those things that "normal" fault does not cover.I have been using the radio for several days, now, and all seems well..I felt the need to let the group know of my experience in hopes that others will benefit...Best of 73's and VERY Merry Christmas...To ALL>

Terry:

I checked and the foil side marking for both the original rectifier board and the replacement one both say "J25-0936-24" So I got lucky with that.

Now I am puzzling over two things:

1. A yellow wire that comes from a terminal strip over by the power output section anc apparently goes to the rectifier board.

2. While trying to figure out where the yellow wire goes I consulted the photos I took of the set at the start of the repair effort and it appears that ALL of the posts on the rectifier board had wires attached to them.

What Fun!

Thanks!

Robert

A few months ago -- inspired by postings from our mutual friend Terry -- I bought a Hakko 808 Desoldering Kit. To date, this purchase has represented the best value-for-money I have ever spent on an electronics repair tool, especially considering the fragility of the Kenwood hybrid and TS-940 circuit board traces I've been messing with lately. Soder-Wick and its derivatives, with their tendency to damage the very delicate Kenwood PCB foil, is now largely obsolete in my practice.

I have recently added a couple more very handy tools to my bench. One is a small battery operated screwdriver. The one I have is a Ryobi model HP53L, though several manufacturers offer similar devices. This little tool makes Kenwood cabinet removal and replacement, with their seemingly scores of fasteners, quick and easy. In the past, I have actually procrastinated on service tasks simply because I didn't want to bother with the tedium of removing all the screws that hold our radios' skins on. No more. The motorized screwdriver actually makes the job kinda fun.

The other new and even more valuable tool is a AOYUE Model Int 936 "Professional Soldering System." It's a temperature controllable, ESD Safe soldering station similar to the much more expensive Hakko and Weller offerings. Okay, it's from China, but is very sturdily built and, after extended use, continues to work perfectly. It doesn't have a digital temperature readout like some other soldering stations nor is it a fully fledged "rework station" (with desoldering feature) like some others, but for precision soldering it's just dandy. The U.S. vendor in Walpole, Massachusetts, a fella named Stan Rubenstein, offers higher end, more feature-laden AOYUE soldering stuff, too.

In case we don't meet again before the 25th -- Merry Christmas!

Hi Mike,

Congrats on your repair. The RL1 relay is one of the most failed parts in the Hybird line up and one of the first areas checked during fault finding, as alot of faults are caused by this little over worked relay. Ken, K4eaa, has avaialbe a daugther board that is a direct replacement for this troublsome relay, far superior in my opinion. Unfortunately, you have found out how easy it is to lift pads due to over heating. The Hako 808 is highly recommended for most work on the hybird boards. enjoy your radio and many years of ham communication

50507. Kenwood Hybrid Net Update (December 14, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-14 23:47:24 UTC
From: Mark Gilger
Topic: 50507 Message: 50507

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There
were 24 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
7 running TS-820(x)
6 running TS-830S
0 running TS-511
0 running TS-511
0 running 599 twins

I was running my TS-830s & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
16 stations checking in under fair band
conditions. He had the following number of radios checking in.

1 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88

December 2014, Saturday☐s net total 44, Sunday☐s total = 37 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Good subject as I am slowly getting a few instruments together for learning and aligning hybrid radios.
Now have DMM, Analogue MM, and Digital Storage Scope

Mike gives a good overview but the availability of that gear in Australia is rare and purchasing from US is not really viable - apart from postage cost, there is the high risk of damage to old fragile test equipment in transit.

So what specs should we be looking for in a frequency counter and rf signal generator? - I don't mind 80s/90s era for my basic needs as the earlier tank like instruments are not very portable!

A few possible models I saw mnetioned
Leader LSG-3215, 3216
Panasonic VP-7633A, VP8131A, VP-8174A, VP-8175A

Regards
Christopher - Vk5LTD

Christopher,

A good frequency counter is the Sinometer VC2000. It covers the 10Hz to 2.4Ghz. It also has a "fundamental" crystal check feature.

Another good frequency counter, without the crystal check feature, is the VC3165 Frequency Counter. It has the same frequency range as the VC-2000, 10Hz to 2.4Ghz.

Another inexpensive frequency counter is the Heathkit SM-2420. It has a frequency range from 5Hz to 500Mhz.

There are a variety of inexpensive signal generators.

1. Heathkit IG-102. I use a frequency counter with mine to ensure the applied frequency is correct.
2. URM-25 military surplus. Heavy and getting harder to find in good working condition

There are a variety of Volt meters.

1. Heathkit IM-5225 FET volt/ohm/ma meter
2. Heathkit IM-5238 FET AC volt meter
3. Heathkit V7A, IM-11, IM-18, and SM-5218 are all very good analog VTVMs.

I have #1, #2, and a few of #3 meters.

DVM/DMM are plentiful. Make sure you pay attention to the meter's input impedance, should be at least 10meg or higher in both AC and DC ranges. I have a list of DVM/DMMs I use on my website

W5RKL http://www.w5rkl.com

W5RKL http://www.w5rkl.com Welcome to my Amateur Radio website. 73 Mike W5RKL email: w5rkl@yahoo.com

View on www.w5rkl.com http://www.w5rkl.com
Preview by Yahoo

Click on the Manuals, Docs, and Mods link and when the page comes up, scroll down to TEST EQUIPMENT SPECIFICATIONS list and click on the link. The text file lists the meters I use and their input impedance ratings.

An inexpensive scope is a good investment. One that has at least 50Mhz rating. there are plenty of scopes on eBay and other on-line websites.

Learn on the inexpensive gear first. Once you have become good at using the inexpensive gear you can graduate to more expensive gear with more features.

Hi Chris,

Yes it's a real problem getting good quality test
equipment down here. Shipping from the US can be
really expensive and some sellers don't ship to Australia.

The Jaycar frequency counter is a good unit that
reads to over 2.6GHz and quite a good price.

The supply of good generators at a reasonable
price in Australia has dried up in the last few
years but they still appear on VKham classifieds
from time to time. VK3XYZ deals in surplus test equipment and is reliable.

Whatever you get, make sure it has a good
attenuator either digital or manual (10dB/1dB
steps) and a good frequency readout or provisions
for a frequency counter output. Don't be afraid
of big cheap boat anchors if you can get one as a
starter - I have a Marconi 2002B which weighs
over 30kg but puts out a nice clean signal down to -127dBm

Good luck with your search

Lou

Hi Chris, Yep, agree with Lou that good test gear is hard to find here in Oz... I'm not sure if you have a specific need to test AM/FM broadcast receivers as the signal generators you have mentioned will do this. Keep an eye out at the Ham fests as well. There are a few reputable people dealing in this sort of gear that attend these events on a regular basis. I saw a HP 8656A going for about $ 275 the other week (as well as a HP 8901 for $ 200) down at the SPARC hamfest.
Keep an eye out for Rohde and Schwarz, Hewlett Packard, Marconi and IFR gear.. all good work horses (plus there are many more brands as well)
Cheers,
Rob VK3BRS

50515. FS: Almost perfect 2 Year old KENWOOD TS-520S station

Yahoo group: TS-520_820_530_830 (2014)

FOR SALE: 2 year old Kenwood TS-520S with matching 520 external VFO w/cable and matching TS520 Speaker. Internal PS, runs off of 125vac.

Equipment was purchased in 1977 and put in the closet when owner went SK in 1979. Equipment had plastic dust covers on all, all this time. Almost perfect.

Does have 2 years' worth of use, plus a little plastic rubbing. Leather handle looks brand new. Operates on all bands, 100 watts output.

Original Owner's manual, Original Sales receipts from Nov 1977. Original Log book 1977-1979.

Absolutely gorgeous! Should not go to a new ham as "first radio". Would like to sell complete for $475. Shipping extra.

OR trade for a later model Kenwood or ICOM; 440SAT, 450SAT, 735. Equipment is to support a public Middle School HAM Club.

Photos available. In Aiken SC area

Off reflector question worth sharing.

Question:

Noticed that the two Omron MH4P relays in my TS-820S have different coil resistance. Why and does it make any difference which position I put them in. Asking as I pulled both and dont remember which goes where.

Answer:

There is a good reason why they have different coil resistance and yes it does make a difference which position. In the past I have responded here that in troubleshooting a problem OK to swap the relays and if problem is fixed then you know relay contacts are the root cause of the problem and not bad molex connector or other source. Now carefully remove lexan cover and very carefully clean the contacts. OR buy a NOS sub relay #401013-S from Kens Electronics in Kalamazoo Mi.

My advice should have been better.

I should have said to check which relay is in what position as you have no idea if previous owners have swapped them and to make sure after any troubleshooting by swapping and/or cleaning to place the relay with the 300 ohm coil in the Ant TR position and to place the relay with the 385 ohm coil in the Aux position.

The 300 ohm relay under metal shield can is what I call the Ant TR Relay and the 385 ohm relay in middle bottom of rig on the Relay Unit board is what I call the Aux Relay. It switches auxiliary functions like rx and tx bias. These MH4P relays have different coil resistances for an important reason and that is timing co-ordination or sequencing of the opening and closing to prevent "HOT SWITCHING" of RF current on the TR relay contacts. You always want the relay contact that is connected to the SO-239 that switches the antenna from the receiver front end to the pi-network output to not actuate whenever RF drive is present. Opening of contacts with rf current on them and RF voltage across them can cause an arc and both contact surfaces can be eroded away prematurely. This effect is magnified with transmission line and higher VSWR (reactive antenna load).

As mentioned the Aux relay performs the function of controlling RF drive turn on and off and it takes something on order of 3 to 5 msec for the RF current to completely decay after the TIF amp, Transmit Mixer, and Driver tube are biased off.

If you look at the MH4P relay in the TR position will see it has 300ohm coil which means approx 40ma current and it will switch faster as it will develop higher current which means higher flux concentration. However, it will also then switch back slower as the flux field will decay slower when the coil voltage is removed. We want this relay to close before RF drive is turned on to the final tubes and we want it to open after RF drive is turned off and rf current has decayed. Lastly if you look closely at the contacts on this MH4P relay you will see one contact that is about 2x the size of all the other contacts. Again this is by design to handle the RF current. Normally approx 1.4 rf amps into 50 ohm dummy load.

If you look closely at the lexan case on the 300 ohm TR relay you should see the letters TRI-2. This is another clue that it belongs in the Ant TR position. By the way you wont find this info in the MH4P data sheets that I have been able to locate. Perhaps Omron made these special MH4P relays for KW? The Aux relay has no such lettering on the lexan case unless previous owner has switched the covers during cleaning exercise. The coil resistance on the Aux relay is 385 ohms which means approx 30ma coil current and slower actuation time and faster contact opening time than the TR relay. To understand this hit the books and refresh yourself on inductors and ELI the ICE man and what happens to current and the flux field in an inductor when it is energized and de-energized.

OK both relays are obsolete. You can use Kens Electronics Fujitsu NOS sub #401013-S which has a 235 ohm coil (50ma). I would place it in the Ant TR location as it should close faster and open slower. However, it does not have that one heavy contact. I would not use it in the Aux position.

Summary:

There is a design reason why the two MH4P relays have different coil resistances and one heavier contact. Place the 300 ohm unit in the Ant TR location and the 385 ohm unit in the Aux position. OK to swap for troubleshooting and then swap back. OK to clean and if cant improve with paper wetted with Deoxit go ahead and burnish with diamond point file (nothing more abrasive than this or could remove design coatings). OK to install Kens NOS sub in the Ant TR position. However, realize its contacts may not last as long as original.

1. Will the rig work if you swap the relays? Certainly.
2. Will it accelerate contact wear? Of course.
3. Will that be measurable? It depends on your length of transmission line and reactive antenna loads you are switching and what condition contact is presently in. Might accelerate contact deterioration by factor of 100X?
4. Is there any way I can measure the contact resistance and what should it be? Yes can use the "6-1" test by applying approx 6vdc across each set of closed contacts and limiting the current to 1amp with series resistor or lite bulb. Then measure the millivolt IR drop across the contacts. Should be under approx 100 mv which equates to 100 milli-ohms. Most hams do not have a milli-ohm meter and simply measure contact resistance with an ohm meter and that is not a good test.
5. Can I electrically clean the contacts if chemical cleaning doesnt help? Yes use a little more power. Suggest trying 12vdc current limited to probably no more than 2 amps and applying across the contact and keying the relay multiple times and then repeat measuring the mv drop across the contact to see if getting any improvement ie lowering the mv reading. Some of what you may be seeing is relay contact actuation leaf damage due to rough cleaning operations and almost impossible to get them back to factory new position, tension etc.

Sorry so long and sorry if I previously advised anyone that it was OK to swap the two relays without telling you to make sure to swap them back in to the correct positions so that they can perform the relay timing sequence that those dumb old KW design engineers intended.

Dont worry about the TS530 and TS830. Need same relay sequencing to avoid hot switching the TR relay but two very different relays employed and not possible to switch their positions. Of course some other issues which have been more than adequately addressed with these two relays.

I have the following items for sale

1. Kenwood R599 receiver. Works fine but the VFO warbbles slightly when tapped. It has both 6 and 2 meter converters installed. $180 plus shpping

2. Allied A2516 ham band only plus WWV receiver. Works very well, no dents, normal wear. $85 plus shipping

3. Heathkit DX-40 CW/AM transmitter, HG-10B and VF-1 VFO, includes a separate power supply that powers either the HG-10B or the VF-1. A toggle switch on the separate power supply, center OFF, determines the B+ and Filament voltage at the octal socket on the supply. They all work fine, normal wear and tear. DX-40 is missing the crystal door on the rear. the VF-1 front panel is not perfect but it does not have any dents or extra hole drilled. $140 plus shipping.

If interested contact me off group.

And how many of us went and opened up their TS-820's to ensure the proper relays were in their correct positions? Mine were! Happy Happy!
There has been so much wonderful tech information here the last couple of weeks that someone probably should write a Kenwood Hybrid Survival Book.

You need to add a message signature to your messages before you post them to the group.

Terry:

Well, things fell into place over the last couple of days. As I mentioned, the "Tan" wire was in reality a White wire. And the real Tan wire went to the voltage divider on the terminal strip you mentioned. The output from the voltage divider is a yellow wire and that goes to STB on the Rectifier Board.

I had photographed the rig before I started taking things apart, and that was a help mainly in being able to see that all of the posts on the old Rectifier Board were indeed in use - although since all the outputs had been severed and jumper wires inserted the photos provided no real help in figuring out what was really supposed to go where.

However, on my working TS-520, 60,000 or so serial numbers later in production than the one being repaired, the Tan wire does NOT go to the voltage divider network but goes straight to the STB post on the Rectifier board. Obviously, there must be some change in the board at the other end of the wire.

I only get to work on the TS-520 repair maybe 1 or 2 hours a day at best, but I am optimistic that I will be able to apply AC power by the weekend.

Thanks to you and Mike for all your help, again!

First a disclaimer - I'm new to the Ham world and working on my test/license. So I listen and learn a lot first.

I was given a TS-830s by a family members and learning about it. I have questions about the accessories for it. I'm sure all would be nice to have but do I really need to spend the time and money on them.

VFO-230 and/or VFO-240 - Do I need either or both or none.

MC-50 - I'm sure the original MIC would be nice to have?

AT-230 Antenna Tuner - Nice to Need?

SM-220 Monitor Scope - Nice (but expensive)

I probably just need to spend my time studying :-) but I'm curious.

Thx
Eddy

Eddy,

You do not need the VFO-230 or VFO-240 to operate the TS-830.
The MC-50 is a nice microphone will work well with the TS-830.
AT-230, I would stick with basic dipole antennas designed and tuned to the band you will be operating in.
SM-220, you don't need that right now.

Yes, spend time studying for your license. Once you pass the exam and obtain your license you will need to gain some experience operating, not looking at or thinking about accessories for your TS-830.

Also, read the TS-830 operator's manual "thoroughly" before you attempt to operate the transceiver. Many operator errors can be avoided if the operator would spend time studying the manual.

I looked at the operator's manual for the TS-520 (one is pdf and the other is Djvu). The pdf copy shows the voltage divider "on the Rectifier Unit" while the Djvu copy show the divider separate from the Rectifier Unit. It appears the STB divider change was done in later versions of the first TS-520.

Eddy,
Welcome and good luck on taking your exam.
The accessories you mentioned are nice, but for someone just starting out, I will suggest sticking with the basics. I still have my 820S. When I started I had that and the MC-50, a second hand Drake MN-4 matching network(manual tuner) an my straight key...and worked 80 countries on 10meters SSB and about as many on 40 meter CW. I did not get the remote VFO until about 4 years after I got the rig.

Learn how to properly operate your 830 with the basics FIRST. A Well tuned up and operating rig and antenna system is much better...that a bunch of extra "fluff" that you really don't need at the start. These items are not cheap..but the MC-50 could be had for a good price..or an old SURE D-104 "lollypop" is also good.
Topics like this generate LOTS of responses...so just be aware you'll get lots of "recommendations." hihi
Just my humble opinion

The first things to procure are:

(1) a dummy load capable of handing 150 watts (or more).
(2) an HF wattmeter (or SWR/wattmeter), preferably with true PEP metering

The AT-230 Antenna Tuner offers no benefit over other good antenna tuners other than appearance – but if you can pick one up that is in good shape at a reasonable price, go for it.

The MC-50 mic will give you good audio, but so will many other mics. That said, I use an MC-50 and consistently get compliments about my audio, so I don’t feel the need to get a “better” mic.

If you have a STB post on the HV rectifier board then no need for terminal strip at the 6146 tube socket or R16/R17 and no need for anything different on the audio board. R9/R10 100k resistors on the HV Rect board serves same purpose to divide 210A in half (approx 100 vdc). Can then be fed directly to the audio board STB terminal to bias on D3.

Hi Eddy,
Welcome to the club - ham and Kenwood hybrid. Opinions are like navels, everybody has one... Here's mine.

I have an 830S also. Purchased new in 1983. I have pretty much everything Kenwood offered for that vintage - purchased as non-essential "toys" over the years. That said, equipment-wise, I can't imagine operating initially without an antenna tuner with SWR and power meters. How else would you know what was going on with your antenna, rig and feed lines? I have always used the AT-230. It has done everything I needed, but any decent tuner will do. I did have a serious wire antenna bug though. Probably my least used pieces of equipment are the external VFO-230 and the SM-220.

Socially and educationally, seek out the ham clubs in your area and find an "Elmer." This would be a guy(s) that would answer the hundreds of questions you'll have and point you in the right direction on equipment, antennas, feed lines, etc., and get you on the air! You have the Cadillac of the hybrids IMHO and an excellent base component of your future station. If you have a local ham radio store (candy shop), you'll find them very helpful too.

My Elmer pointed me to the TS830S and accessories. I have been in his debt ever since. Also, in hooking up with hams in your area, you'll find them very generous. My Elmer gave me some equipment to use on "permanent loan." That meant I could use it until he needed it - which he never did. After 31 years, I still have his Collins R390. Since you don't have a callsign yet, I can't determine your location. (Look me up on Hamcall or ARRL.) I have some items, like a surplus MFJ 300W dummy load that you could have on "permanent loan." You'll find local guys that will do this.

In acquiring additional equipment, IMHO, eBay is over priced. Best bargains can be found at ham fests, estate sales, etc. I recently purchased a Heathkit IM-18 VTVM at a ham fest for $8. They go for $40-50 on eBay, including shipping.

Good luck on your test. A little studying and you'll find it a piece of cake. BTW, sites like ARRL and eHam are very generous with helpful info. Join them. And free practice exams are all over the web. Just make sure you get the current question set. The FCC changes these every few years. If you prefer books, ARRL is the place to go.

I have a TS 530S that I left working and next morning Very poor Rx sensitivity. Only the very strong signals come through.

I suspected a front end blow up as I might have accidentally transmitted from from another radio in the shack while the 530 was connected to antenna.

Opened the radio and measured Voltages across Q1on RF board. The Voltage on AGC gate should be 2.4 Volts according to service manual. It was 0.710 volts. Replaced Q1 which is a 3SK73 with a 3N200. Still same situation. Same voltages. The transmit is 100 percent perfect.

Any pointers guys ? Thanks in advance

vu2yk,
(pse include ur name next time. tnx)
It is quite possible that you have fried "L-41," which is the antenna step up transformer...and marked as "1.8" on the RF board...and maybe...I think D-2...which it right next to it. It is not uncommon. Can you get a good strong "cal signal?" If you can inject a signal prior to L-41...if the injected signal is not there or very, very weak...versus a signal injected after L-41 is loud and strong...is quite likely that L-41 got fried. Hey it happens!
Unfortunately, L-41 is no longer available from Kenwood. The options are: rewind it(a short tutorial diagram is available in the "files section" of the group...thanks to Gordon/n6wk(SK) with #42 enameled wire and LOTS of magnification..and a steady hand, or find a good known goodone. I have heard of someone winding a toroid to approximate the value of L-41...but I do not recall who, or the procedure used 73 Joe

Very hard for average ham to accurately measure the AGC control voltage on Gate 2 of any of the gain controlled mosfets. Need very high input Z meter. One of the best is a HP-410C with over 100meg input Z.

Absent that kind of meter use a 11 meg VTVM. After that a 10meg DMM but make sure it is 10 meg on the range you will be using. Many DMMs are range dependent and can be as low as 2 meg input Z on the lower voltage ranges and will really drag down the AGC bus. Even a 11meg VTVM will pull the normal 3.2vdc down approx 0.60vdc to around 2.6 vdc or lower and drive the S-meter upscale. Not knowing what meter you used it is possible you pulled the AGC bus voltage down to 0.7vdc attempting to measure it.

Only way you can have 2.4vdc on Gate 2 is if you have RF gain wide open and RF-1 set to approx 3.2. Then if you measure with 10 to 11meg meter it will pull AGC bus down to around 2.4 to 2.6 vdc. Have to be aware of the effect of your meter on measuring ACG and ALC bus voltage as both are high Z power supplies and cannot support any current.

The way you can tell if your meter is adequate is set RF gain pot to full CW position and see if the S meter is at zero. Now touch meter probe tip to Gate 2 on Q1 or just on the AGC terminal at Molex connector 5 and if S meter moves up scale your meter is pulling the 3.2 AGC bus voltage down. With experience you will learn how much is due to meter and how much indicates a problem. By KW listing Gate 2 voltage as 2.4vdc you can be pretty certain that they used a 11meg VTVM to make the measurements.

So I would measure my RF-1 and make sure it is close to 3.2vdc and then measure AGC bus and see where my meter pulls it down to. If it pulls down 0.6vdc can be assured will pull down Gate 2 to that level or slightly lower.

Not very common to loose Q1. Much more common to loose L41 ant step up transformer due to inadvertant transmit RF.

Easy to trouble shoot. If you have RF sig gen then inject 50uv signal (-73dBm) at the wiper of switch deck S1-2. If no RF sig gen then use mini-grabber test lead and jumper the Marker signal to S1-2. Looking down on the 2nd red/brown deck from above just left of the band switch shaft at approx 1130 will see S1-2.

I cannot part with any of my rewound L41 transformers as reserved for my customers. You might try Dick Housden W0NTA to see if he has one he will sell.

Greetings Group!
Well, another year is almost gone, and we're still here!

I wish I could thank everyone eye to eye, but that's just not possible.So, thanks to all group members for making this the "place to go forall your KW hybrid needs." I want to especially say thanks to:Mike-w5rkl- group moderator, and Terry-k9tw. Both have assisted thisgroup and its many members, both here, and also on their respective web sites, with their extensive knowledge and assistance.
There will be some very minor changes coming shortly. OK...don't freak out...it's very minor...and just involves some rewording of some "auto send" messages that NEW members to the group will get, and possibly a mass email to all group members regarding the change. If you already follow group policy by properly signing...this will have no effect on you. So, just to sum it up..it just involves proper identification of posts/msgs....ya know...name & call(if any) and not calling the "administrators" naughty names... hihi

I hope everyone has a safe and happy Holiday Season, and remember the men and women serving this country that can't be home with their families! It's because of YOU, that WE are here.....

From: ku4a@...
Topic: 50538 Message: 50538

I have a TS-530S that receives fine but I've been told the transmit audio is distorted. Listening to a carrier from the rig in CW mode, I hear a good bit of buzz. In general, the power output won't go above about 10 watts.

Is this typically a failure of an electrolytic capacitor in the high-voltage supply? It would be good to know if there are other things I should check as well. It would be nice to avoid having to deal with those high-voltage caps, but if that is the problem I'll replace them.

Chris,
What does your HV read on the front panel meter? The meter is not 100% accurate, but will give you a good idea. Properly tuned up on desired band and key down, you should see approx 750+VDC, if it's approx half that then you have probably lost 1 of the HV electrolytics.If that is so, replace BOTH. Several kits are available: k4eaa.com and Hybrid Restore(Jim-a7oj).
Is this rig new to you, or have you had it for some time and the problemjust started?

Terry:

I went back and read again your and Mike's comments on the STB post.

So, given that the TS-520 I am working on has a rectifier board that has the STB post, and also has the divider network (and always did have both, apparently) should the yellow wire from the divider network go to the 210A post or the STB post? Right now I can only assume it went to the STB post originally.

Thanks!

Robert

50541. Re: Missing Wire on a TS-520

Topic: 50447 Message: 50541

If you have a wire from the center of the two 100k ohm resistors on the phenolic terminal strip that feeds STB on the Audio board I would connect the Yellow wire from the terminal strip to 210A on the HV rect board. Otherwise you will have divided 210A in half to feed the STB post on Rect board and then divided it again by half at the terminal strip to feed STB on Audio board. Would result in approx +50vdc at the Audio board and that is too low to overcome -66vdc that Key supplies.

Suggest you lift the wire off the STB post on the AF board and then temporarily land the yellow wire on 210A and STB a the Rect board and measure the voltage obtained in both configurations at the lifted STB lead to chassis ground.

STB at the Audio Board should read approx +100vdc and not +50vdc. This is from memory but pretty sure it is correct.

Maybe someone who presently has covers off their TS520 can measure STB post on Audio board for you to validate what I am telling you.

You need positive voltage applied to anode of D3 to forward bias it to close the RC feedback loop to get Q6 to oscillate. D3 has two power supplies feeding its anode. One power supply is the +100 vdc fed from STB thru a 1 meg resistor and the other power supply is -66vdc fed from Key thru a 220k resistor.

With the code key up the -66vdc applied to the Key terminal post bucks the +100vdc and D3 is reversed biased. That keeps Q6 from oscillating ie no side tone. With code key down or closed that -66vdc becomes approx -0.25vdc. Now the +100 from STB forward biases D3 thru 1 meg resistor and completes the feedback circuit.

50542. No Transmit - TS-830S

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-19 06:02:58 UTC
From: rrmvargo@...
Topic: 50542 Message: 50542

I am trying to make my 830S parts unit a working unit. I got the display & receiver working. But no transmit. All tubes light. Just a budge of ALC and no bias at all. I found R11 470R on the rectifier board to be open. I replaced it & upon plug in, it smoked right away. I quickly unplugged the radio. I removed the driver tube (I see that one of the 210A connections goes to the screen, have yet to find the other 210B???) & turned the bias control fully counterclockwise, and got the same result. It is late & I'll continue to investigate tomorrow, but thought I ask here to see what are the likely culprits.

Also, is there an EZ way to lift the rectifier board? Thanx – Bob W8RMV

210B is the pulsating dc output of the SG supply 1/2 wave rectifier D6 and the filter capacitors for it are on the back right corner of the IF board. It is what we would call a Pi filter or a CRC Filter. R11 replaces what would have been a choke in the old days. The Pi filter consists of C180 22uf and R11 470ohm and C181 22uf. The filtered DC from this CRC filter supplies the R122/R13 divider resistors for STB, the screen grid voltage for the Finals, and the Screen grid voltage for the Driver tube thru divider resistors R36 and R37. R11 sees the combinded screen grid current of the three tubes and the two sets of resistive divider current as its load. People tend to blame the sg current as reason for R11 failure and there is seldom a sg grid failure inside the tubes.

Most likely cause of R11 burning up is shorted C180 and C181 on the IF board. Ken K4EAA sells a set of 4 of them so you can also replace the 300B anode supply filter caps at same time. I always recommend customers replace these as cant see the rupture vents and hard to ESR them in place. So if going to pull IF board to inspect and or test then might as well replace all 4. Normal ESR will be approx 1.0 ohms.

Sometimes R36 fails but it usually goes very high or open and not shorted.

If you pull the IF board to replace the filter caps take opportunity to inspect every molex connector soldering.

I forgot to mention that after you install filter caps you can measure the current thru R11 by measuring the IR drop across it.

I have couple of SMD thin sharp meter probes that I can use, but absent that kind of probe can use floral arrangement pins (available at craft stores) and mini-grabber test leads to prod down inside the insulating spaghetti sleeving on each resistor lead. Be careful as dealing with approx 250vdc here.

With rig loaded to 100 watts out into dummy load should see approx 12vdc to 13vdc across R11. I = E/R

or 13/470 = 28 ma. So anything from around 25 to 30 ma is the design load that R11 sees. If see much more than this then need to look at the two divider resistors, but as I mentioned my experience they tend to go high.

Wattage = I squared R or .030 x .030 x 470 = .42 watts. I would use a 1 watt resistor.

Who needs that stink-in Ohms Law stuff!

One correction. As I mentioned you cant see the 22 uf rupture vents as mounted on the PC board, but you can ESR by prodding down inside Conn 14 Pin 1, 3 and 4. Should ESR around 1.5 ohms.

Just have to try to fold the board over to a at least a vertical position towards the xfmr. I have seen a few replacements of R11 by cutting the leads close to the resistor body and tack soldering the new resistor to the stub leads using care not to apply too much heat and melt the solder at the PC board pads.

Thanks, Joe. I will take a look at the high voltage. "Properly tuned up" is somewhat problematic for this radio as it generally acts strange when attempting to tune up. But I do get some power out with LOAD, PLATE and DRIVE at or close to expected settings.

I bought this radio awhile back to complete my collection of Kenwood hybrids. When someone told me it sounded bad on transmit I put it on the shelf as a "project radio". Now, in retirement, I am starting to work on it. It's in very good shape cosmetically and the receiver is excellent, so well worth the effort.

Status report:
I removed the IF board & immediately saw the issue. Somehow one of wires on the molex connector had the insulation nicked and the conductor was visible. Plus the last cap, C181, also had the vinyl wrap nicked & the 2 were in contact. Probably happened when the last corner screw was installed. I checked all 4 caps & they were all right around 1.0 ohms for ESR. I forgot to check them for value. Of course I know this does not mean these old caps will be good tomorrow, but since it is a parts unit, I did not put the new caps in. I fixed both issues & reassembled the radio. 60mA Bias was now working as well as the ALC. In fact there is almost too much ALC on 80M as I recall (if I try to keep the ALC in the zone during tune as some suggest). But I can never get to 225mA into a dummy load. Only 80-160mA Ip, depending on band and a max of ~80W out. Some bands were in the 40W range. I believe I was getting ~12-14W during tune. I did go thru the coil pack adj. & drive just in case, but although some were off a bit, it did not help all the way.

So I still have some work to do, but it is getting closer to good parts rig.

Thanx for the help! – Bob W8RMV

Joe:

Thanks but have to say this year that Mike has carried the lions share of the load.

Been a very busy year for me. I appreciate all the members who sent rigs to me and/or made referrals.

I do try to check the post daily typically in early mornings with my coffee, but just cant devote the time that I use to. Also get quite a few off reflector requests and some phone calls for help.

There are several fellows who when they do come out of the shadows demonstrate they have good fundamental backgrounds and provide technically accurate info and of course a couple who persists with voodoo stuff, but suspect their intentions are good.

I have given up on all the other forums that give advice on KW hybrids as I was spending too much time correcting bum dope and defending my responses. Never want to take advise from someone who says "I dont own a KW hybrid but here is how my Yaesu worked back in 1975"!

We are lucky to have this forum and I know that the admin burden isnt easy.

Wish you and all members much Happiness, Prosperity, and most of all Good Health in the New Year.

Topic: 50542 Message: 50557

There is no such thing as "too much" ALC indication when adjusting the Drive control. That is like saying the Driver stage grid and plate tuned circuits have too much "Resonance".

You are tuning the Mixer LC circuits and Drive coil LC circuits simultaneously to resonance so that you have maximum RF voltage swing (approx 47rms rf volts) at the 6146 control grids. When that happens you will have a control grid that is positive with respect to the cathode and a very very small grid current will flow (ranges from approx 35ua in middle of the black box to approx 45 ua at meter FSD). That is Micro Amperes and not Milli Amperes. Not possible to exceed the 6146 control grid dissipation. Not a Class C CW transmitter.

When that ua grid current flows it causes the ALC amp transistor (which is configured as a dynamic negative low voltage zener diode) to produce approx -1vdc at its Collector which is series opposing the 3.6vdc ALC bus voltage. The ALC meter circuit is a voltmeter that monitors the ALC bus voltage and when it drops from 3.6 the meter indicator moves off zero up scale. The higher it goes the lower the ALC bus voltage and the lower the RF drive voltage to the 6146 control grids. When the bus drops from 3.6 it immediately reduces the TIF amp gain and the RF drive drops and the 6146 grid current cannot exceed approx 40ua or so. None of the meter scales mean anything. Just a way for you to know you have tuned the Mixer and Drive LC circuits to resonance (the frequency where you have the VFO set at). Resonance means max Z which means max RF voltage. All the 6146 control grids need is RF voltage swing sufficient to overcome the dc offset of the operating bias. NO Grid Current is required or desireable for a Class AB-1 grid driven tetrode linear amplifier. We are not using ALC as a measure of grid current. We are using it to tell us when we have max RF voltage at the 6146 control grids. We will have that when we see a Peak in ALC reading and that peak can be anywhere on the meter scales. Just as Relative RF output power can be.

I have talked about this until blue in the face. If it makes you happy to keep the ALC indication within the black printed scale have a ball. I often tell new people if it is easier for them to do that so that they have to commit only one rule to memory then go ahead and keep it withing the black range. That way it assures they will be more likely to do so when modulating in SSB mode when the black range does mean something.

If you can get full scale ALC deflection on all bands then you have a good TIF circuit, good TX Mixer, good Driver tube stage, and good bandswitch contacts switching in the band specific respective Mixer LC circuits and Drive Coil LC circuits. It means you have approx 47rms rf volts at the control grids of the 6146 finals.

Low RF output power then can be attributable to:
1. Bad RF plate choke, bad Plate block/coupling cap, bad RF bypass cap
2. Soft 6146 final tubes
3. Low DC voltages at the 6146 finals tube socket pins especially screen grid voltage
4. Bad fixed padder capacitors
5. Bad Ant TR relay
6. Bad solder connection at the SO-239 connector and/or loose lock nut.

If low power on all bands then not likely that all the padder caps are bad.

Time for me to get back to work.

Terry K9TW

Didn’t mean to make anyone blue in the face or take anyone away from their work. I specifically used the word “suggested” to soften the statement some, knowing of past statements pro & con, but only to describe an observation. I have worked on 2 other 830’s & don’t recall such ALC action. When I post here, I am never sure what observations I should post, knowing I risk taking the post into the ditch if not careful. And then there is pg 18 in the manual. Which brings me to the common statement found here and every group & that is to: read the manual. Pg. 18 speaks to keeping the ALC within the “range” and it also says “on-scale”. It is no wonder that this comes up on occasion. Hams are doing what many ask; they are reading the manual. Therefore, this will come up again. Perhaps an errata sheet should be written that replaces that section on pg. 18 and a requirement that all members read and understand

Thank you for your other suggestions. I have already installed the final cage repair kit from Ken & I had tightened the SO239 and checked the solder joint. Have not checked the padder caps, ant. relay, etc. As this unit was a smashed, dirty, nearly deaf, no display, non transmitting unit when I got it, I am pretty happy how it looks & performs at this point. A little more work will make it 100%. – Bob W8RMV

Yes it is the single most question that new folks ask about the loading procedure and Kenwood finally with the 830 model simply revised the manual to say keep it inside the black range. Wish they had not done that but it was the easiest thing for them to do.

I dont expect you to take me at my word or anyone elses word on this or any other technical subject on any forum. What I am suggesting is that you think and validate what you read, hear and see. This one is very easy to validate. Place you DMM from VR-2 to FG on the audio board and measure the IR drop across the series combo of R101/R102 while you use varying amounts of Car Level to place the ALC indication any where on the meter scales. You will read approx 0.8vdc. .8/200k= 40ua of grid current.
You can also read from FG to the Emitter of Q19 but have to be careful not short out Q19 leads. There you will read from 0.35 to 0.40vdc. .4/100k = 40ua of grid current.

Lastly dont you think if it was important from standpoint of exceeding the 6146 control grid dissipation or any other limitation that KW engineers would have been smart enough to list the precaution in one of the earlier model operating instruction manuals? No from day one they simple state to peak the ALC indication and if no indication simply increase the CAR level until you get an indication that you can peak.

There can be several reasons why any KW hybrid (not just TS830 model) may require differing levels of CAR pot advancement for adequate ALC indication. Not going to expend the keystrokes. Will just say it all begins at the Balanced Modulator. A good fully functional and properly aligned TS830 should get full scale meter deflection (FSD) with the CAR level pot advanced to no more than #3 to #4 position with exception of 10 meters which may require #5 to #6 position. If you cant get yours to do that nothing to worry about as long as you can get a discernable peak you have adequate RF voltage swing at the control grids. I prefer they leave the bench in the former condition.

That's a good way for members to learn by actually performing the measurements Terry mentioned.

It's the same method I used in my Ohms Law training videos. I perform the calculation using the correct Ohms Law formula first, showing the results (answer to the problem), then tell the viewer to take out his/her calculator and perform the calculations themselves, using different values so he/she sees what happens to the circuit's voltage and current levels when a component value changes. You won't see the actual results if you don't spend the additional time performing the actual measurements. In many cases, not all, the member actually learns by "Seeing is believing"!!! Oh, one more thing. While these simple Ohms Law measurements may appear silly to some, remember one thing!! When you actually take the time to perform the measurements using your DMM, you are actually learning how to perform basic troubleshooting steps using a piece of test equipment, so you get 2 for the price of 1!!!

We ALL went through the same basic learning steps when we started out. For those who are just starting out, trying to learn, you are going through the same learning process we went through!!!

Sorry Terry, didn't mean to jump in and change your response. I'll back out and let the thread continue.

50562. TS530 antenna relay replacement (using NTE parts) effort

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-20 16:39:12 UTC
From: Jan Servaites
Topic: 50562 Message: 50562

I have successfully found the right parts, after a painstakingly long research effort, to replace the soldered in antenna relay in the TS530. Mine was bad and now my 530 is working great.
I used parts from NTE including the relay and socket. Its a higher amperage relay contacts too. And my relay repair is a "bolt-in" installation, without any sheet metal trimming but does require moving some parts around, but it looks factory good. Soldering the wires to the new relay socket is easier too, I think.
I'll be on the Kenwood net today with the newly repaired 530. I made some DX contacts last night on 40M with the 530, its working really well now.

Mike no problem. You are of course spot on. You and I have talked basic electronics applied to RF communications and how to acquire the needed foundation many times. Of course it is not easy to acquire basic RF communications fundamentals and people learn differently today. In our day common to learn knowledge items by reading and learn skill items by doing and practice.

You and I read and took courses and did the calcs and did the related bread boarding and got a sound foundation in basic electronics and as you say the bread boarding and testing and measuring part proved to us that the theory works and helped us learn how to use test gear.

I think today to tell new folks they need to start reading the ARRL handbook, John Fryes Basic Radio Course, Elements of Radio by Marcus, Termans classic text etc just isnt going to happen in about 99% of the cases. Simply takes too long when you are use to instant answers on Google. I still tell them to obtain these and similar texts and build a good reference library. I would be lost without mine.

So in my case coming up under the old licensing structure, having a passion for learning and understanding along with a little aptitude helped me. In addition to that foundation the way I have learned how the KW hybrids work was by looking at the Block Diagram and reading the Circuit Descriptions and studying the Schematics. This only takes you so far as not always a lot of meat on the bones with the circuit descriptions.

For me where I really gain knowledge is when I encounter an operational problem. I study the schematic and try to understand the design. Coupled with that is taking a lot of readings both DC and Signal on a fully functional radio and then marking up the schematic and/or keeping good note books. Of course I am into over approx 260 units at this time so I can see test points in my sleep on most of the rigs and have quite a bit of info committed to memory, but still rely heavily on my mark ups and notes.

I dont claim to understand every circuit and every transistor amp or oscillator configuration, but I have a pretty detailed understanding of how AGC and ALC works.

Mike you can jump in at any time especially when it comes to doing a QC on my responses. I often do real quick back of envelope calcs and sometimes slip a decimal or two! You and I are getting to be dinosaurs and we really need to get some of the younger folks coming so they can hold up the tent poles when we are not around. I have seen a couple of fellows on here grow quite a bit in last couple of years. They shall remain nameless so they dont get a swelled head!

This is the 4th 830S I have worked on. I have not worked on any of the prior models. I have not studied the prior models. I've never worked on any Hybrids before except for another 830 before I became a Ham a few years ago.. So I wouldn't assume they are the same. Assumption is one of the worst things I do. Almost always gets me in trouble.

But I am past that & understand the posts, yet remain at the elementary level for the radio. Thank you. Now to further stick my neck out....

I went back thru my unit checking for reasons it is low on Ip and output. After going back thru things, some of the ones you just mention, it is now putting out 100W+ into a verified dummy load. But the Ip is running way low. I am getting 100W with current about 50% of what I'd expect. Which then makes me suspect the 60mA of bias. So I pulled the PA board to check R10 & R6. R6 is 2.7k, but R10 is 9.8k & marked as so, and looks original as does the solder job. The schematic I have shows R10 as 4.7k. Comments? The SN of this unit is 1030253.

Jan,

Great work, will be interested in seeing how you have achieved this, as I have seen several with very ordinary retro fitted relays. My original 1984, 530s has a plug in antenna relay that was retro fitted by the local Kenwood agent when mine died, now is the same as the 830s. I have a fully restored re-built fully filtered 1987, 530s, so will be interested in seeing what you have done, why re-invent the wheel when someone else has spent the time. Whilst people say this antenna relay isnt available, I know of a place in the States that still has original NOS, but not at $US45.00 each plus $US47.00 p\h.

R10 was a Fix by KW engineers to address the possible negative effect of blown cathode resistors ie blown panel meters due to the open cathode rising toward 6146 screen grid voltage any time you have an arc over and the cathode resistors blow open. In a matter of seconds the open cathode rises to well over 100 vdc. Measure it next time you blow you cathode resistors just dont place the meter in the IP position while you have rig energized with cathode resistors removed. Of course if it is a 530/830 will have to lift one leg of R10. None of the other KW hybrids have an R10 resistor.

The meter may have survived the initial arc over and very high IR drop across the cathode resistors (will most certainly slam hard against the peg during the event). What most of us would then do is try to load the rig again as not sure what just happened. When we do that and place the meter in the Ip position it now sees that 100 plus volts for a brief time until the 800 ohms of the meter movement can pull it down. It wont like that very much. So KW added R10 resistor to the 530/830 models and it is in parallel with the cathode resistors and it doesnt blow when tube arcs over and it prevents the cathode from being open circuited during arc over event.

So now you have R10 in parallel with the four 20 ohm resistors. The higher the value of R10 the less effect it has on the parallel combination and the accuracy of the plate current reading is minimally effected (about a needle width). You can prove this by lifting end of R10 and loading to say 100ma and then tap R10 on and off the solder pad and watch the needle. Of course can calculate it by using rules for parallel resistors but wont do that here.

Depending on what model and series production run rig you have you will most commonly find a 4.7k ohm or a 6.8k ohm resistor. Either one will work. Later runs used the 6.8k ohm.

I have a short write up on my website under the FAQ describing why KW added R10. R6 2.7k is the series meter multiplier. It takes the 500ua meter movement (800 ohms int R) and makes a voltmeter out of it. Instead of actually measuring current by placing panel meter in series with the cathode KW employs common voltmeter method of displaying current by actually measuring the IR drop across the 5 ohm meter shunt.

I forgot to mention your thought process is good to question the IP metering circuit.

If you have accurate external wattmeter and getting 100 watts output into a 50 ohm resistive dummy load then you cannot be loaded to 100ma.

So logical place to look would be at cathode resistors. However I find that the original carbon resistors most commonly drift high in value which should give you a false high Ip reading or a conservative failure.

If you are uncertain about accuracy of your wattmeter and you have O-scope or RF millivolt meter or RF probe capable of measuring approx 71 rf volts you can place a coaxial tee on your SO-239 and measure the RF voltage to chassis ground at the open ended Tee. If you really have 100 watts out then you should read close to 71 rf volts. Need a 3 diode RF probe if dont have other test gear.

The only reason I mentioned about concern over Control Grid dissipation is that this is the most common misconception about loading a KW hybrid. I read this on most of the other forums from old timers who think ALC is displaying ma grid current and back in their day and mine the first words in the loading instructions in the manual was Caution Dont Exceed 3ma or 4ma or 8ma as we had our Heath 6146 transmitter meter in the Grid Current position to peak the Drive. Of course this admonishment was spot on correct and necessary with a Class C CW transmitter that we were all loading. I assumed you were in that camp based on your call sign and talking about keeping the ALC indication within the black printed range. I should have asked why you think you need to do that or why those that you cite think they need to do that. The very worse video I ever saw on You Tube an Extra Class holder discussed at length the importance of setting the ALC there and when all done loading must go back and readjust if it had changed and even used the Drive control as a level control which of course just detuned his receiver!

I checked the cathode resistor resistance & it is 4.8R. I then pulled one end of each & was surprised to find each was just under 20R. I feared that one or more had uncharacteristically, gone low. Whereas R7&8 were up to 135R. They were the 30+% I have expected on older stuff. I replaced those.

I put it all back together & took it upstairs to check it on my Palstar AT2KD where it again tested over 100W into a 1.5KW DL. HV reads ~840VDC & Ip is at 95mA, that is not 100+ W. So I will continue to puzzle on this. The implication is the 60mA bias is actually 120mA, but somehow don't believe that. I need to study the schematic more. I know it is not a meter issue as the meter can swing past full scale with ease, given that excessive ALC! ;-) (pls notice the wink)

The suffix of my call sign are my initials, nothing more. I am just someone early in the learning curve and some one who likes Kenwood Hybrids. They are a lot of fun compared to my contemporary radios. I'll have to admit that the Yaesu FT902DM has caught my eye also. Both nice looking radios. And unless you are willing to give me a Hybrid Vulcan mind transfer, I will never achieve your level of understanding or some others here. Even if I was smart enough (doubtful), there aren't enough years left in life to do it. That is why this group makes the life of all Hybrid owners a lot better.

After I get the meter/Ip issue fixed, I'll be back for some suggestions on VFO TC1/L3 tracking adjustment for this unit.

Thanx for the help. - Bob W8RMV

Bob

I assume you have measured the operating and cutoff bias voltage at the 6146 tube socket pins on the Final board? I would also measure the Screen grid voltage key up and key down there as well. The voltages will be close to what you see on the schematic.

Bob,

If you doubt the Ip meter indications, which is appears you do and I don't blame you because 95ma is not the cathode current at 100 watts output, you can simply measure the final tube cathode voltage. If the cathode resistors are within tolerance, 20 ohm each resistor, then you should measure approximately +.3VDC cathode voltage with 60ma flowing in the final tubes in either USB or LSB with MIC gain set fully CCW with transmitter keyed.

E = I x R

or

/*.06 x 5 = .3*/

Now, measure the cathode voltage with 100 watts indicated on the watt meter then use Ohms Law formula

I = E / R

to calculate the approximate final amplifier cathode current. You said the cathode resistances measured 4.8 Ohms so use that as the value for "R" and the actual DC cathode voltage you measured as "E" and you will find the cathode current "I". Then compare your math to the IP meter at 100 watts output and I suspect you're going to see a significant difference in the IP meter display verses the actual voltage and resistance values used to calculate the actual cathode current.

Preview by Yahoo

It is reasonably priced & works very well where a conductive lubricant is required. It has a conductivity spec. It was the first grease that I could actually measure its conductivity with a DVM.

I even used it on the problematic 12 pin connector that is found at the back of the counter board on a TS830S. But please note that a very little amount goes a very long way. A tube will last a lifetime for most. It is also works well on the roller follower on the roller inductor of a tuner. Also know that if you smear it, it will act like a wire or a resistor to the surrounding area.

For the connector mentioned above, I put a small amount of grease into a ink refill syringe & added a few drops of 99% alcohol to thin it. I then inserted the needle into the female end of the connector & squirted just the tiniest amount into each opening. The needle was the perfect size. That connector and the counter has worked perfectly ever since. This was after cleaning the contacts, re-soldering the pins, etc. to no avail. - Bob W8RMV

Mike & Terry,
I will try to make those measurements today or tomorrow. I also plan on checking the Ip wire itself and the switch.

I did transmit for the first on it last nite on SSB 80M and was getting 100W out, but I was told the audio was really bad with excellent signal strength. ALC was acting a bit weird. It was either there or not as I adjusted the mic control. Since the radio got smashed at the mic corner & I replaced the mic connector, I will look there first. The mode switch shaft was also broken. No need to take the discussion there, but just wanted to report. - Bob W8RMV

Of course you know you can listen to your audio with headphones and the Moni turned on. I would do that into dummy load as you troubleshoot and try different mics and settings etc. A very nice feature to have. That way dont have to put signals on the air until you think close to ready.

First I apologize to the group for the extent of this thread & lack of due diligence on my part. I have an aversion (I've grandkids that seem to like me for unknown reasons) of checking the high voltage areas, even tho I know the safety precautions.

I measured the screen pin 3 at 124VDC both at the final board & at the SG board itself. That, of course, is way low to the 264/222VDC spec. Pin 5 was at -98VDC. So I need to investigate that SG board more. Plate is ~920VDC. I get 0.31VDC at the Cathode at 60mA bias or right on the money. And this is where it gets weird, I get 0.48VDC cathode voltage at 90W on 40M and the Ip meter reads correctly at about 95mA (I=0.48VDC/4.8R). BTW, I am using a Fluke 189 for all my voltage measurements so I trust the readings. I don't have Hi RF voltage measurement capability.

900VDC x 0.1A x 60% efficiency should be about 54W. I am messing up somewhere.

So maybe I need to take this off group and do a better job of analyzing & measuring before coming back. I'll fix the SG voltage & report back. Thanx. - Bob W8RMV

50578. Hum in VOX

From: junkmailsux@...
Topic: 50578 Message: 50578

I get great reports on my TS-520 except when I try to use VOX. When I use VOX there's a buzz or hum in the audio. I don't have an issue using the PTT on phone but I was thinking about trying some digital modes. I can't afford a RIGblaster so I need to build a simple interface.
Feel free to assume that I have very little electronics experience.

Thanks!!

Date: 2014-12-21 19:40:49 UTC
From: Mark Gilger
Topic: 50579 Message: 50579

et Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There
were 24 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
2 running TS-530(x)
5 running TS-820(x)
5 running TS-830S
0 running TS-511
0 running TS-511
1 running 599 twins

I was running my TS-830s & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
31 stations checking in under fair band
conditions. He had the following number of radios checking in.

8 running TS-520(x)
5 running TS-530(x)
2 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88

December 2014, Saturday☐s net total 65, Sunday☐s total = 68 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:

Didnt this all start with a burned up R11 and I am pretty sure that I gave you the IR drop you should read across it to see if the SG supply was seeing normal load current.

I think I also described the location of the loads and common failure on divider resistors on the RF board. Also suggested that you check the two 22uf caps in the CRC filter on the IF board? I think you said you ESRd them but didnt bridge them. I wouldnt worry about bridging. Big capacitance tolerance.

It sounds like you have a bad C180 or C181?. At least most likely source of fault current.

I think you pulled the IF board and said you saw a shorted lead wire of some kind in this area? I would take a hard look at those filter caps again and probably change all 4 as 30 plus years old and can cause some collateral damage. I have seen very badly burned up IF board at these caps as well as a bad carbon track on the HV rect board right below where R11 mounts.

What I am saying is it doesnt sound like you found the root cause of burned up R11 470 ohm. Anytime you have to replace R11 good idea to measure SG voltage at HV rect board and at the Finals tube socket pins. I also load the radio and measure the IR drop across it to make sure load current is not excessive. I guess I just assumed you had done that.

OK -98vdc is cutoff bias in Rx mode need to measure the operating bias in with rig flipped to send. My guess is it will be around -60vdc based on what you describe about your ALC indication in Tune Mode peaking the Drive. If you had -98vdc bias voltage in TX mode would have no ALC indication at any CAR level pot setting.

If still have same low Plate current and low RF output issues after getting the SG voltage to normal then try another set of finals to rule out soft finals. Can just load on 40 meters and not worry about neutralizing for a quick test.

I suspect once you get the SG voltage to around 225vdc or so key down you will have normal plate current and output power. This will probably be a lesson on how SG voltage affects operation of a Tetrode.

Terry:

I have the cover off my working TS-520, sitting just a few feet away from the TS-520 being repaired, so I can use that as a reference source if required. However I note that the pictures I took before I removed the failed rectifier board show that something was attached to the STB post - and I don't know what it would have been if not the yellow wire from the voltage divider. But that may mean nothing, or at least very little, since all of the rectifier board output wires had been clipped and replaced with jumpers by a previous owner.

So I am getting close to firing this rig up again. I'll let y'all know how it works.

Thanks again!

The wire that shorted to C180 leads directly to 210B on the Rectifier board. So I am pretty certain that was the reason for R11 to fail. All 4 caps on the IF board checked OK but I replaced them anyway. No change. But when I measured pin 5 on final board in transmit, that is way off of your estimate & print spec. It pulls down from -98VDC to -41VDC. I will try another set of tubes in the days to come. - Bob

Topic: 50542 Message: 50584

OK I guess I forgot you replaced all 4 caps. Then need to look at the HV rectifier board and measure SG voltage at 210A. It should be approx 260vdc. I have never seen either 100 ohm grid stopper go high enough to cause big IR drop. I have seen a open L2 470uhy choke. If open then no SG voltage. Not likely but could have a very high resistance contact on the SG switch. Just cycle it back and forth a few times. Make sure the lead wires to it our soldered well and not broken and just barely touching.

The reason operating bias is at -41vdc is because that is where you have the bias voltage adjust pot on the rear panel set. You have control over where you set the operating bias voltage.

It would be very rare to have an internal short on the 6146 screen grid. You could remove both tubes and make sure that the Anode caps are in the clear and then power the radio. Now you can adjust bias voltage pot for -60vdc at Pin 5 and measure the SG voltage at Pin 3. If voltages are good then shut down and discharge the HV caps and reinstall the tubes and repower and repeat the measurements. If now bad voltages then have a problem with one or both tubes.

Well probably best to trace it or ring it out to see if output of the divider does feed the STB post on the audio board.

You can of course measure the voltage on the STB post on the HV rectifier board that has nothing landed on it. It should read approx 100vdc. If it does cant use that to feed the voltage divider terminal strip as would end up supplying only 50vdc to STB on audio board. Could eliminate the divider resistors on the terminal strip and just use it as point to connect lead from STB on HV rectifier and STB on audio board.

Topic: 50542 Message: 50586

Terry,
I pulled the SG wire from the final board to separate it from the finals, ie- trying to spilt the dictionary, The SG voltage did not change. Given that, I felt the issue is on the rectifier board or maybe said a better way, it is not on the finals board. 210A measures 127VDC at 210A. I sprayed the SG switch days ago thinking it could be that also. No change. I need a few days free of this unit. I'll try the 6146 removal test then.

But I appreciate your help/endurance. If I find the reason for the low SG voltage, I'll be sure to post it here. Thanx - Bob W8RMV

Bob:

Turn off the SG switch and read the voltage at Pin 3 at tube socket. Should be approx -110vdc or so.

I dont know how it would be possible for you to have both 210A and -C supplies in parallel? If you had that -C would buck 210A and give you what you are seeing.

This is controlled by small RL-1 relay on the Rect Board. When you close the SG switch it grounds RL-1 relay coil which has 12vdc on at all times and SG-2 switches from 210A to -C. SG-2 becomes SG-1 which becomes PD-2 and feeds the screen grid terminal on the Finals board.

I have never had to replace the small relay and not sure how could get both supply voltage through it at the same time unless a carbon path on the board?

Mike please jump in as I may be missing something obvious here.

50591. TS-530SP RF Gain

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-22 07:15:27 UTC
From: tghotdogz@...
Topic: 50591 Message: 50591

Hello to the Group,
Haven't posted in a while, but I have an issue that hopefully one of the experts in the group can assist me with.
I picked up a TS-530SP today and upon getting home gave it a quick check. The radio does receive, although sensitivity may be a bit low, but the radio is not deaf by any means. The S meter only deflects slightly, even on very strong signals. The calibrator gives between an S 2 and an S 4 depending on the band - this with the S meter sensitivity pot on the IF board maxed out. The main problem, (which I suspect is related to the low S meter reading), is the RF Gain control has no effect on either the meter or signal receive. The transmitter section appears to work normally. I downloaded both the operating and service manuals, and will print them out tomorrow.
I've worked on several 830's, and a number of 520's and 820's, but this is my first 530 and I've never run across this exact issue on any other radio. I'm assuming the problem is in the AGC circuit?
Any advice on any known problem spots to check, or other suggestions would be very much appreciated.
Regards
Tom

"Craig Laboratories", the maker of DeoXit D5, F5 Fader cleaner and lubricant, as well as other contact cleaner's and lubricants, also sells a conductive grease

/*DeoXit L260Ap

*/This grease comes in various size containers and application methods. I purchased the grease in a 28gm plastic container for $13.69 "Free Shipping" on ebay ad #181243982516. It appears he has raised his price by $2 since I purchased the grease from him. You may find it cheaper from other eBay sellers or at other on-line outlets. It only takes a small amount to complete the job, same as the contact cleaner.

Depending on your usage, the 28gm container could last you a very long time.

Have you measured RF-1 and adjusted it as necessary? Also look at RFG on the IF board molex Conn 12.

Terry,

Measurement at Pin3 on either 6146

T=tune r=rec s=send CW=CW
SG off -
Tr-53
Ts -51
CWr - 114
CWs - 110

SG on-
Tr - 53
Ts - 39
CWr - 126
CWs - 89

I initially sprayed contact cleaner on the SG switch but deoxit also before measurement, as it still seemed a little stiff compared to my other 830s.

That's all until after the holidays. Happy Holidays All - Bob W8RMV

Bob

Are you saying you are measuring negative voltage at the Screen grid with SG switch ON? I thought you reported positive 126vdc or about 1/2 normal SG voltage?

If negative then check RL-1. Watch it as you flip the Screen Grid switch on and off. You should be able to see and hear the armature movement. I dont know how the NO (normally open contacts) could have gotten welded shut?

OK we can pick back up after X-mas

Some of those PA wires are solid core 22 or 24ga wire and I have some
that fractured and broke. I have replaced the yellow, screen voltage
supply wires on all my rigs with Mil spec, teflon/silver wire.
Check all of those PA wires at the soldered ends, thats were I found the
breaks.

Bob and Terry,

The only way pin 3 of the 6146 tube sockets will have negative voltage with the SG switch set to ON or OFF is if the SG switch is not working properly. There is a error on the 830 schematic that shows the SG switch in the "OFF" position yet the Rectifier Unit's relay RL1 is NOT energized!!

If you study the 830's schematic's Rectifier Unit's "SGS" (Screen Grid Switch) terminal as shown on the right side of the Rectifier Unit schematic, you will see it connects directly to the SG switch's SPDT terminals. Follow the wiring up to the SG switch and you will notice the switch is shown in the "OFF" position yet the Rectifier Unit's RL1 relay is NOT energized.

The Rectifier Unit's RL1 relay voltage is routed through the MODE switch wafer S18-2. When the SG switch is set to OFF, relay RL1 on the Rectifier Unit is energized resulting in the Rectifier Unit's -C supply, approximately -101VDC or so, to be applied through the Mode switch (any position) and through the path to the final unit's "SG" terminal, hence the 6146 final tube screen voltage is "negative" not "positive".

The SG switch position, based on the Rectifier Unit's relay state, should be shown in the "ON" position.

I should have added the following:

Naturally if the SG switch is working properly and the switch is set to OFF the final tube's screen voltage will be negative and positive with the SG switch set to ON, regardless of the MODE switch position.

Hi Ron,

You didn't say if the -6V supply was also missing. If it and the 9V are both missing then I would chase the 14V line. If you have -6V then your problem lies somewhere on the AVR board. If you haven't already done so please download a large format circuit to help with your troubleshooting.

Topic: 50542 Message: 50602

I get an email everytime someone responds & I feel bad waiting till later to respond. So I run back to the torture chamber & make a few measurements & run back upstairs to type.

In worrying about how Yahoo was going to reformat my post, I screwed up on it. Here is how it should look:

T=tune r=rec s=send CW=CW
SG off -
Tr-53
Ts -51
CWr - 114
CWs - 110

SG on-
Tr+53
Ts + 39
CWr + 126
CWs + 89

I also suspected the SG wire, but found the same voltages on the Rec board. FWEIW, I checked all the diodes on the Rec board & they are good. Resistor measurements compared to my working unit were also close except for one resistor that is a 12k vs 15k in the later 2M SN. Relay seems to work as I see it actuate & I popped off the cover to see how it affected the R15 & 16 and it does.

I also ran the no 6146 test (nice trick) and no joy. Screen voltage is still low with no tubes.

I have started to measure all the wire wrap pins to compare with my working 830 and think I have found some anomalies that I will report on later maybe next week.

So I really must go & thanks for all the tips & education..... Bob W8RMV

Hi Linas,

If you haven't already done so please download a high resolution circuit from here.
http://www.n6wk.com/kenwood/TS-820S-%20High%20Res%20Schematic.pdf

S1 is the meter switch and according to the circuit is supplied from the HV unit. You will find S1 and the meter in the top right hand corner of the circuit just below the coil pack unit. You should firstly check the voltage at HV & 800 on this board. Of course it should be clear that there is high voltages on this board so work carefully and make sure your meter is capable of measuring up to 1000V. You migh also need to check contacts RL-3 and the wiring to the final unit involving MR1 & MR2 on the final unit.

Mike: Yes fully aware of how it works and the error on the schematic.

What I am trying to understand is how he is measuring any negative voltage at the Screen grids with the SG switch OFF. I thought he reported about half positive voltage and now appears to report always a negative voltage regardless of switch position unless it was a typo.

Switch wired wrong.
Switch broken internally and stuck in OFF and not actually toggling internally
Bridged /Welded RL-1 contacts

????

OK this is better! Not good but believable!

One other thing to check is the AC voltage of the secondary winding that feeds your 1/2 wave rectifier. Not likely that it is bad but easy to measure at AC210.

How did you install the new R11? Did you fold board over and unsolder and resolder or did you tack it on the stub leads on top side of board?

Its not likely to have a high resistance wire wrap at 210A. What do you get if you measure off R11 lead?

Lets get it correct at the Power supply and then see if correct at the tubes.

Terry K9TW

Smoking gun?

One thing you guys forgot to ask me (see it's all your fault ;-)) is: what is the AC voltage at SG? I finally remembered to always check for AC on a DC line when trouble shooting. Well there is a ton.
Tr 39VAC
Ts 41VAC
CWr 87VAC
CWs 102VAC

That is why I can't get to the right screen voltage. But I still haven't figured out why I have AC there.

So it seems I have half a bridge out but where does that thing go. My eyes are going cross eyed on the schematic. PD2 is derived from SG1 which goes over to the switch then back over over to .... C1/AC100?? That makes no sense. It looks like only the caps are on the IF board. I lose the path. I know, I need Ken's Blow up. Since the diodes check OK, maybe I have a bad ceramic?

Topic: 50542 Message: 50607

Bob,

PD2 and SG1's path goes back to the MODE switch SG1 (wiper). Depending on the position of the MODE switch determines what source the voltage comes from the Rectifier Unit.

In TUNE, the MODE switch TUNE terminal routes back to the Rectifier Unit's "TUNE" terminal and the R15 and R16 resistive voltage divider that reduces the screen voltage applied to the final unit's SG terminal by 50%.

The SSB and CW MODE switch terminals go back to the Rectifier Unit's "SG2" terminal on the Rectifier Unit where normal screen voltage is applied to the final unit SG terminal.

The Rectifier Unit's SG2 terminal voltage comes from the Rectifier Unit's "210B" terminal through the Rectifier Unit's RL1 relay!!!

The 210 supply is a simple half wave rectifier consisting of diode rectifier D6 and a simple PI input capacitive filter consisting of electrolytic capacitors C180 and C181, both 22ufd 350VDC mounted on the "IF" Unit and resistor R11 on the Rectifier Unit.

How do you know the voltage on the final unit's SG terminal is AC? Did you look at the SG terminal with a scope? If there is, in fact, AC on the final unit's SG terminal, did you check to ensure the 2 wires that leave the Rectifier Unit's 210A and 210B terminals to the IF Unit's C180 and C181 are not disconnected at the Rectifier Unit??? That's the only way you could have pulsating DC on the final unit's SG terminal is if those 2 wires are disconnected from the Rectifier Unit. If those wires are in fact disconnected then the 210 supply's PI filter is NOT in use, resulting in pulsating DC on the final unit's SG terminal and the driver tube screen through the RF Unit's plug 9 pin 2.

50608. TS-520S - Sell, Salvage, or Fix

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-22 21:13:53 UTC
From: 003402
Topic: 50608 Message: 50608

I am a relatively new ham (Tech in January, General in October) and decided to get a 520S as a starter rig after doing some research on good options.

I found a local 520S that was in good working order. After getting a walk through on the operation, and the previous owner making a final contact with it, I transported it home. After a quick setup and check out, I found that it wasn’t transmitting. It seems to receive fine on a few bands (I am still getting the hang of the antenna tuner and such). Have listened in on many conversations on 20m with no issue.

I checked out some of the obvious things that might have happened during transport (e.g., SG switch is on, Ext VFO jumper in place, MC-50 cables in the right order, all seemed ok). I peeked under the hood and no loose wires or anything obvious.

I took it to a local shop to see if they could fix the transmitting problem (They do not specialize in Kenwood Hybrids). They were able to get it fixed (to a degree, it transmits on full power on SSB and CW all the time), but the receive failed. They were troubleshooting the transmitter issue and the tech said that he heard a pop and the unit no longer received. He called after that to see where to go. He indicated that it could get costly to continue to fix/troubleshoot. I had him stop and would retrieve the unit. I really can’t afford to have a tech continue to spend time/$$ chasing the issue on a rig of this age.

So, the question is: Do I sell it to someone that can do the work themselves (I don’t think I have the skills to do it), part it out, or try to troubleshoot it/repair myself. I am not yet comfortable enough with my electronic skills to be tinkering too much for fear of wrecking the machine, or worse myself, so the last option would be a long term endeavor. In the meantime, I will be without an HF rig for the foreseeable future.

Thanks in advance for any advice. This group has been a great resource and while much of it is over my head at the moment, I am picking up valuable knowledge.

73,
Robert/KD0YMC

Mike,
When I was checking voltages between my good 830 vs the one with low screen voltage I was checking from ground to the SG terminal on the Final board with my DVM.

As you know, there is a mix of AC & DC on the rectifier board and I was seeing a strange mix of AC & DC on some terminals. If I take the AC voltage I see at SG measured this way, and multiply it by 1.4 and add that to the DCV I see there, I get to the 260VDC I am supposed to see. When I check for ACV on my good unit, I see mV or just the ripple. So this is why I suggest it is the smoking gun.

I need to digest a bit what you described as the circuit operation. Am I wrong in my analysis or approach?

Bob W8RMV

Robert,

Sorry to hear about the loss of receive in your rig. Have you verified that it still transmits after the pop and with no receive?
Or is this a case that while they were tweaking the transmitter, they heard a pop, noticed that the receive was gone, shut it down, and called you?

73,

Bill, WA6NEQ

I took it to a local shop to see if they could fix the transmitting problem (They do not specialize in Kenwood Hybrids). They were able to get it fixed (to a degree, it transmits on full power on SSB and CW all the time), but the receive failed. They were troubleshooting the transmitter issue and the tech said that he heard a pop and the unit no longer received. He called after that to see where to go. He indicated that it could get costly to continue to fix/troubleshoot. I had him stop and would retrieve the unit. I really can't afford to have a tech continue to spend time/$$ chasing the issue on a rig of this age.
So, the question is: Do I sell it to someone that can do the work themselves (I don't think I have the skills to do it), part it out, or try to troubleshoot it/repair myself.
I am not yet comfortable enough with my electronic skills to be tinkering too much for fear of wrecking the machine, or worse myself, so the last option would be a long term endeavor. In the meantime, I will be without an HF rig for the foreseeable future.
Thanks in advance for any advice. This group has been a great resource and while much of it is over my head at the moment, I am picking up valuable knowledge.

Houston, we have ignition! Based on that little explanation (thanx Mike) I knew the next steps. I then pulled the harness that goes to molex 4 on the IF board and rang each wire, but all were good. So then I went pin component side to foil side & they were good. Then I went from pin foil side to the next connecting component & bingo! No connection from pin 2 to the cap buss. Fixed that & now have 264VDC at SG & no AC. That pin 2 was really messed up almost crystallized. Maybe the shorted wire had something to do with that. Wished I'd measured the ACV at the get go. My little calculation was good.

Anyway, thanks to all for the help, endurance and patience on this one. Did I set a thread record?

THIS. If not him then someone in the local area. (There is probably a club in your area or close enough to get to on a weekend now and again.)

You --need-- to get some electronics experience if you want to get the most out of this hobby. It's what makes it FUN! Tinkering with a modern all-digital rig is NOT going to help much. But a hybrid has circuitry (and components which are large enough to actually SEE and MANIPULATE!!) which you can understand. And once you understand even a little of it, you will be much more likely to be able to apply that knowledge to gaining more, and so it snowballs.

Just memorizing test question answers does not a good operator make, I am afraid. Too much of that going around in my opinion.

Do at least give fixing your hybrid a try. Get help from whomever you can, including offers from folks on this list. You're a long way from me, I think, or I would loan you some gear and see if we couldn't get you up to a safe speed inside that 520S.

Good luck, hope you at least try it. Challenge yourself. Keeps your mind active, keep you YOUNG even when you get to be an aulde pharte like me.

Terry,

I have verified RF-1 properly set at 3.2 vdc. RFG voltage on IF board connector 12, pin 4 varies between 0.75 vdc with RF Gain control fully CCW, and increases to 3.2 vdc with RF Gain control fully CW.

Any other thoughts or suggestions as I move forward?

Regards

Tom

Have you measured RF-1 and adjusted it as necessary? Also look at RFG on the IF board molex Conn 12.

Tom:

I was hoping for an easy fix.

Have you tried tapping on the plastic cover on the aux relay on the IF board with the Marker on and watching the S-meter. Its contacts switch the AGC bus voltage. Sometimes lite tapping will cause better contact closure.

You can measure the AGC bus voltage at the IF board and at the RF board molex connectors but your meter will pull it down. If using a DMM with known 10 meg input Z on low voltage range you should see the 3.2vdc pull down to something around 2.6vdc or little lower.

You can also temporarily apply 3vdc from couple of flashlite batteries to the AGC pin on Molex conn 6 on IF board and if rig comes alive then you know something is pulling down the AGC bus. Usually if the meter FET is bad you wont have any receive and the S meter will be pegged.

Do you have a good RF signal generator? Can inject test RIF signal to see if the IF chain is good and if so then you know problem is on the front end (RF board).

I am getting close to being able to fully power up the TS-520 I have been working on. I'll still have to make some new covers for the power amp section and the relay area on the bottom, but I will apply power and see what occurs before I do that.

So far I have replaced the rectifier board with one that has been rebuilt, including new C1, C2, R5, and R6.

I have replaced C-27A/B, C-28A/B, C-31, C-32, C-33, C-34, and what I think is C-42, a 470uf 16V cap (I used a 470uf 35V cap).

I examined the two 10 ohm resistors in the power amp section and found them to look new and apparently are metal film caps. Resistance of each I measured at about 5 ohms, but of course it is hard to get good measurements at that resistance range.

So, any recommendations on what else I should replace before proceeding further? Of course, the radio came without a 12BY7A or 6146's, so I will be replacing those as well.

Thanks!

Robert

Forgot to add:

Inject -43dBm or approx 1.6mv @ 8.830 mhz into Conn 1 Pin 3 (RIF) on IF board. This should give you approx S9 indication if the gain controlled devices are seeing appropriate level of AGC bus control voltage.

Robert,

I am wondering if you are saying that each final amp cathode resistor is 5 ohms? I could be wrong but I think you meant to say that the final amp's cathode resistance measured about 5 ohms which would mean each cathode resistor is 10 ohms. You have to lift at least one lead of a cathode resistor to measure each cathode resistor's actual value. You can't measure each cathode resistor with both resistors wired in parallel.

If the final amp cathode resistors were in fact 5 ohms each, that would result in a total cathode resistance of 2.5 ohms which would result in a lower DC voltage applied to the IP meter resulting in erroneous IP meter indications.

This is off-topic but, seeing that the Azden PCS-3000 does not have a same cult following like the Kenwood hybrids, I figure I publish it here.

Below is a link to my blog on how I transplanted a newer Mitsubishi RF Amplifier Module into my PCS-3000 in order to replace the defective Taiyo RF Amplifier Module that is no longer available.

Maybe this will inspire you to dust off that old Azden in the back of your closet and give it a second chance!

Hi John,

Even though it is way off topic I think you need
to spend a little more time on that radio.

You need to ensure that new module is screwed
down properly onto the heatsink (with heatsink
compound) or you might be replacing it at some
time in the future. Looks like you only used one screw.

I think you should spend some time trying to
figure out why the fuse blew on low power -
doesn't that seem illogical to you? I don't know
but could it be that in low power mode something
changes in the way the module is connected to the
RF deck? Could it be that in Low Power mode the
module was biased in such a way that it drew too
much current or a supply line got grounded?

If you heard the fuse "pop" then I suggest you
have a serious issue in the radio that should be
addressed. One day it could come back to bite you.

Regards

Lou

50626. 830s QRP mod

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-23 21:25:39 UTC
From: Steven Springer
Topic: 50626 Message: 50626

I tried this mod with the 9V battery, a 100K pot and a cable with positive to connector shield and negative to pin 6 on the remote plug in the back. Tuned radio for 100 watts out on CW and applied the - voltage slowly. Nothing happens, no decrease in output. Opened up the radio and did the same with no AC power on the radio. Monitored the - voltage swing between D19 on the AF board and chassis with a DVM. Have a nice 0 to almost -9v swing as I turned the pot hooked to the 9v battery. So I know my circuit is good. The explanation for this mod says it is effective in both CW and SSB.

The only problem I have noted with the radio is the ALC meter pegs to the right when modulating in SSB. It will peg and return to zero repeatedly. As it is doing this I monitor my transmit signal (sm220) and it appears good with no clipping and the audio reports I get are also good. Maybe unrelated problems but thought I would mention it in case it rang a bell with someone. I have spoken to a few other 830S owners who have same issue with ALC meter pegging but output audio is fine.

I am trying this QRP mod so I can tune up a linear amp by slowing increasing the drive. Any suggestions are appreciated. I have a DVM and an oscilloscope.

Topic: 50624 Message: 50627

The footprint of the new Mitsubishi RF Module is smaller then the original Taiyo. I secured it with only one screw because I didn't want to risk drilling/tapping a new second hole and having the metal chips short something out. The one screw holds it firmly in place.

Good catch, I used heatsink compound when mounting the new RF module but forgot to mention in the blog.

I could find very little information on the original Taiyo RF module and the Azden manual does not have specifics on low RF power is achieved through bias so I was left my own devices.

Yes, it is an imperfect solution, but, maybe someone can built on my adventure to come up with a better one.

John

Mike:

I measured the two resistors while they were still in the circuit and got 5 ohms each. I verified that they are marked as 10 ohm resistors and that they look like relatively new metal film resistors.

I have not done the analysis to see what the value should be in the circuit but if it is 10 ohms or less I figure that they are Okay. I believe the normal failure mode is to fail open? In any case, I don't really trust the measurements of my DVM on resistances that low - I think you need a special ohmmeter to get a good reading even when they are out of the circuit. Most of the time, on the lowest range when I short the leads of the meter I cannot get it to read lower than maybe 25 ohms.

Thanks!

Robert

Hi Robert,

There's something wrong with either your meter or your leads if you can only read 25 ohms. Even junky meters will read close to zero ohms when you short the leads together - certainly under 2 ohms. Some DVMs have a ohms zero function which allows you to compensate for lead resistance.

Whilst you might need a specialized resistance meter if you want to measure very low resistances with precision any DVM should allow you to easily read 10 ohm resistors within +/- 1 ohm and certainly much better than that.

Are you certain that you are on Pin 6? It can be a fooler. Appears you are if you can see variable negative voltage at D19.

This method works in both CW and SSB modes by simply bucking the positive 3.6vdc ALC bus voltage. If it didnt work in CW mode how would you ever set it for SSB mode? Not very convenient to have to inject audio signal into the mic line. Just adjust the pot to reduce the output power to what ever level you want in CW mode after loading to 100 watts output and that is the output power level you will be modulating at in SSB mode.

The ALC bus must be powered and operational in both modes otherwise you would have no control voltage on the TIF amp gate 2 and no TIF output to drive the TX Mixer.

The 830 uses two different ALC time constants for CW and SSB modes. Q20 is used to change the time constant by switching in and out RC network C60 and R98. KW and other mfg commonly do this as form of RF speech compression to increase talk power by slighlty increasing the peak to average ratio. Q20 switch is turned on in SSB mode which produces a time constant that has fast attack/slow decay.

You can see the RC time constant by connecting O-scope to the ALC bus and keying rig and speaking into the mic using five-five-five for example. Can also watch it in CW mode and see the rc time constant when keying.

If you are certain you are connecting your variable source of negative voltage to Pin 6 and chassis ground then only other possible reason it is not working in CW mode is open L2 or open D19 or open D21 (very rare failures).

ALC should not peg the meter in SSB mode. Have you performed Step 31 in the service manual?

I forgot to mention are you sure you turned the pot sufficiently?

You will have to apply approx -6vdc before you start to see any reduction in the ALC bus voltage to begin reducing RF drive from the TIF amp. This is due to the series zener.

I went to tune up my 820 and after allowing ample time for everything to warm up, began the tuning process. First step was to check the plate current to see if it is at 60 milliamps. I did so and it was low, with a a little wavering in the needle. Are my finals toast, or could it be a faulty driver?

Kenny,
It is possible the T/R relay is sticking. It is right by the final amplifier board on the underside of the rig. With power OFF and rig UNPLUGGED...make sure that the HV caps have no voltage..check at the "800" terminal on rectifier board. Remove the metal cover and remove relay. You will need some type of contact cleaner...many use DeOxit, and some stiff card stock. Remove the plastic cover on the relay...wet a long thin piece of card stock with cleaner and run between the relay contacts...you will probably see some black residue on the paper...that's good. You will have to manually actuate the armature to get the other contacts clean

OK, this is operator error. I was tuning up with the send switch and this ckt being part of the AF board made me think that I needed some audio. I hooked up my key and keyed down a solid tone--and wahhla!! the ALC -vdc cuts the output power from full to zero as I adjust the pot. These rigs are a real learning curve for a new guy but lots of fun. The Kenwood operating manual isn't exactly the best at explaining this rig either. Not real clear and also the manual shows the RAL signal from remote jack going to the IF unit and not the AF. I think they were better at making radios than documenting them,, HA!

Thanks Terry,

I made a reply before I saw your post. Things worked fine after I hooked up my key and sent a solid tone. Just using the send switch in CW mode doesn't work since there is no audio I figure. I will check your suggestion on the ALC pegging issue. Thanks again.

Steve:

Not true.

You do not need to key the rig with a code key in the jack for this mod to work. If you do have a code key in the jack then you need to flip to Send and key the key or turn on the VOX and leave rig in standby and key the key to adjust the pot.

Simply load like normal in CW mode to 100 watts out. Dont reduce the CAR level pot. Now connect your new 9vdc negative supply to Pin 6 and simple flip to Send in CW mode and increase the negative voltage to provide any lower level of RF output power you want in CW mode. OR if you leave key in key jack do as noted above. Now you are ready to operate QRP SSB mode. You use the mic gain as normal.

If you are only going to run QRP CW mode you dont need this mod. You can control the output power by setting the CAR level pot to any level of output power you want.

Using this mod you are varying the gain of the TIF amp by varying the DC control voltage (ALC bus) being applied to Gate 2. Using the CAR Level pot you are varying the signal level applied to Gate 1 of the TIF amp.

The only reason you would use this mod is to be able to operate QRP in SSB mode. OK to use it for CW mode but only really need to use CW mode to adjust where you want output power to be in SSB mode.

Some people will tell you that the mic gain is your rf output power control in SSB mode and that is wrong for several reasons. You want to maintain the proper audio to carrier signal level ratio to the Balanced Modulator so you will have proper carrier suppression, you want to maintain the proper Peak to Average Ratio (PAR) for adequate talk power, and you want the ALC to be able to function properly. Never use the Mic gain as your rf output power control for SSB mode.

Lastly what documentation shows RAL going to the IF board? I know of lots of issues with the 830 documentation but dont recall seeing that one?

Steve

I forgot to mention you will not be able to use ALC indication to adjust your mic gain in QRP operation.

Depending on where you adjust the negative supply voltage to Pin 6 you will have a very high standing ALC indication or the indicator will be pegged hard against the peg. If you have a standing 20 to 30 over you would have to set mic gain nearly full CW position to get any upward flicks of meter deflection.

I dont like having a pegged meter so I would switch my meter off ALC and place it in the Ip position and then will have S meter function in receive and will see small upward deflection of Ip from the 60ma resting current level on modulation in SSB TX mode. DO NOT try to talk up the plate current to some high level. If you do the ALC will still work and drive ALC bus down even further but you wont be able to see it.

If you are using a MC-50 or MC-60 mic just set the mic gain at #5 or 1200 position and speak normally into it as you would at 100 watts.

An inline peak reading wattmeter would be best way to set the mic gain.

I recently came across a decent TS520, works as it should on 14mhz and above, on 3.5 and 7 mhz it doesn't want to load up and none of the controls has any effect, no output power at all, HV is steady at 800v. When keyed in Tune mode, IP shows 110ma and in CW IP is 280 on both 3.5 and 7mhz. It is putting out 100 watts CW on 14, 90 watts on 15 and about 80 watts on 10 meters, roughly 800v @ 225ma on those bands, I am using an external watt meter into a dummy load. Any suggestions on where to start trouble shooting this issue? Receives great on all bands. I have it on the bench and am going to start with cleaning controls and switches. All suggestions will be greatly appreciated.

Terry,

Thanks for the guidance. Okay, first up I also checked the 9 Volt AVR line – it was at 8.5 volts. Set it to 9 volts, now S meter will no longer zero – goes down to about S 3. Also now strong signal only moves the meter about 1 S unit.

I tapped on the aux relay – no effect.

I measured the AGC bus, (Heathkit IM-5228 VTVM), and read approx. 2.1 vdc.

When I applied a separate 3 vdc source to the AGC line, noted a significant improvement in receive sensitivity - no effect on S meter.

Injected 8.830 mhz signal at RIF on IF board, (SG is an HP 8640B), at -43 dBm moved S meter about 1 S unit – the same amount as the calibrator. Had to increase to -10 dBm to get S 9. I did not do this while still on the external 3 vdc AGC supply.

During all of these tests, RF Gain control had no effect.

Other thoughts?

Tom

Subject: RE: [TS-520_820_530_830] Re: TS-530SP RF Gain

Tom:

I was hoping for an easy fix.

Have you tried tapping on the plastic cover on the aux relay on the IF board with the Marker on and watching the S-meter. Its contacts switch the AGC bus voltage. Sometimes lite tapping will cause better contact closure.

You can measure the AGC bus voltage at the IF board and at the RF board molex connectors but your meter will pull it down. If using a DMM with known 10 meg input Z on low voltage range you should see the 3.2vdc pull down to something around 2.6vdc or little lower.

You can also temporarily apply 3vdc from couple of flashlite batteries to the AGC pin on Molex conn 6 on IF board and if rig comes alive then you know something is pulling down the AGC bus. Usually if the meter FET is bad you wont have any receive and the S meter will be pegged.

Do you have a good RF signal generator? Can inject test RIF signal to see if the IF chain is good and if so then you know problem is on the front end (RF board).

From Bill, WA6NEQ

Sorry to hear about the loss of receive in your rig. Have you verified that it still transmits after the pop and with no receive? Or is this a case that while they were tweaking the transmitter, they heard a pop, noticed that the receive was gone, shut it down, and called you?

Bill, thanks for the response. It was pretty much the second scenario. I think they chased a few things after that, but my impression it was going to be a lot more $$, so they called me and shut down trouble shooting. I hope to get more info when I pick up the unit next week. Will post with more details.

From Jimmy WB2KNR

DO U HAVE A CONTACT PHONE NUMBER YOU CAN BE REACHED AT?

Thanks for the offer. I haven’t picked up the rig yet, but would truly appreciate the assistance with troubleshooting. Will shoot you my number off list.

From Wes, N9KDY

Appreciate the feedback. I have been drinking from the knowledge firehose since getting my general, spending just about every free moment tinkering with antennas, doing research, etc. Challenge so far has been finding good, hands-on electronics training locally and haven’t been successful so far with the club (another story). That being said, I am continuing on my education however I can get it. I am working on an old shortwave radio, attempting to bring it back to life (a low risk tinkering project), and I built a DG-5 replacement from plans/circuit board. For the rig, I will get a list of the issues wrong with it and assess from there. In the meantime, have printed a large format copy of the schematic and some of the transmit and receive diagrams to familiarize myself with the details. If you all have the patience for my questions, I think I will give it a go.

Thanks all
73,
Robert/KD0YMC

Did we discuss checking the Product Detector carrier null?

If not perform Step 11 of Service Manual. If carrier (carrier insertion oscillator or BFO in old days) is not nulled it will leak back thru L10 and couple thru C31 to the AGC detector diodes just as a strong off air signal would and will cause the AGC amp to be turned on and pull down the AGC bus voltage and cause a standing S-meter indication. Do this alignment step first. I always clean the trimmer pots and caps first with Deoxit and blow out with canned air and run thru range a few times as they can be pretty noisy and touchy. If you dont have RF millivolt meter can use O-scope to adjust the null. Make sure you are adjusting on the Product Detector and not the Balanced Modulator.

Regards the S meter raising the 9vdc regulated supply to 9vdc level should not affect ability to zero the S-meter. Ordinarily you would align the IFT and do the Coil Pack alignment before calibrating the S-meter. You can skip these steps if confident rig was pretty well aligned at one time. Try perform Step 17 of the Service Manual to see if you can get the S-meter aligned. Dont skip any part of these steps. (8dB = -105dBm and 40dB = -73dBm). If have trouble with Step 17 I would go ahead and do Steps 12 and 13 and then repeat Step 17.

Regarding AGC bus voltage I assume you read 2.1vdc on AGC bus with rig on dummy load, RF gain full CW, and I believe that you previously reported that RF-1 is set at 3.2vdc. That is pretty big drop in voltage for the Heath 11meg vtvm to cause. I would have expected around 2.6 vdc or so. That .5vdc lower control voltage on the Gate 2 of all the IF amps makes big difference in gain. We need to figure out why the AGC bus is at 2.1vdc and not 2.6vdc. Lets eliminate Product Dectector carrier null first.

Hello Terry,

Page 13 fig. 3-4 has the ACSY connector which looks to be the remote connector. It shows the RAL to the IF unit from pin 6. A check on the schematic shows it goes to the AF unit.

As for the QRP mod I don't know what was wrong. After many attempts to make it work, I removed the covers and monitored the voltage swing at D19 so I know my cable was correct. Putting it back together I tried the CW key down tone and it worked - so I figured that was the issue. After reading your last post I tried it again without the key and it also works. Probably I didn't have the plug seated all the way the first time and it was sending me on a wild goose chase and/or I may also have a lurking issue with the plug I noticed my VFO plug in the back has a crack in it and probably will fall apart at some point.. Anyway it works just fine both ways and I really appreciate your input - especially all the extra stuff on the way those RC ckts work. I print that stuff out and file it in a notebook for future reference.

Thanks again 73's

Steve K0SJS

I would advise Robert to remove the probes then short the probe sockets with a short wire. If this simple test results in less than 1 ohm resistance displayed on the meter then the probes are the source of the problem. If the test results in the same 25 ohms displayed on the meter then the meter's at fault.

There are plenty of good quality DMMs being sold on eBay, Mouser, Amazon.com, Digikey, and other on-line websites. I have 3 DMMs, Rolls MU-118, BK 66B7000, and Excel DT9205A. They all have 10Meg input impedance in all AC and DC ranges. Also, a good VTVM is a good item to have. I have a few Heathkit VTVMs, V7A, IM-18, SM-5218, and an Eico 232. I also have the Heathkit IM-5225 FET volt/ohm/ma meter. I have 2 Heathkit IM-17s battery powered FET volt/ohm meters that have AC and DC volt meter ranges to 1KV and resistance ranges from Rx1 ohm to Rx1M in 4 ranges . The IM-17s are good for field use where AC power is not available. All of these VTVMs and FET volt/ohm/ma meters are good additions to a shack in addition to DMM/DVMs. VTVMs can be found on eBay, some with probes and some without probes, all at various prices. Probes are easy to make if the VTVM comes without probes.

I remember this problem now. The version of the TS830 manual that you have has the figure copied from the TS-180 operating manual. It is Fig 5.3 page 24.

Now question is how in the world did they get Fig 5.3 from the TS-180 manual copied into the TS-830 operating manual? You can download the TS-180 manual from Gordon N6WK site to confirm.

I dont know of any single source that has compiled all the errors contained in the KW hybrid documentation. Some are just typos and some are grammar due to translation, but the ones that really hurt are just technically wrong.

Jan

If you are asking where to inject test RIF signal on TS830 IF board I simply inject at Conn 6 Pin 6 RIF. No need to unplug molex connector.

I do this test when I am performing split search. Inject audio or touch test lead and a finger to wiper of AF gain pot tells you Audio stage is good. Inject 8.830 RIF at IF board tells you gain controlled devices, AGC, product detector are all working on IF board. You essentially have 4 or 5 key blocks for receiver or transmitter. For receiver Low voltage power supplies, Audio, IF, and RF. Usually very easy to quickly prove each block is working or not.Then can focus troubleshooting efforts to stage that is bad. I almost always rely heavily on signal injection and signal tracing, I have good idea of the required goes ins and goes outs and when I find them missing or low in level I then revert to measuring Dc voltages such as CBE or DGS at active device. Very seldom find bad active devices. Most common is bad molex connectors, cracked PC traces, bad relay contacts etc. So many needlessly replace good transistors and mosfets.

I use floral arrangement pins and mini-grabber test leads. Just prod down inside the Molex connector plug. These pins come in 2.5 to 3 inch length and will have a plastic ball or pearl drop head on them. I slip spaghetti sleeving over the metal pin leaving room for the sharp prod end and leave a space between ball head and shaft at top to clip on the mini-grabber.

I also have an adapter I made by heat shrinking couple of butt splices connectors on piece of bare copper for applying signals and measuring on the PVC board rectangular test post. You can see a picture of it and one of the floral pins on my website.

Jan

I forgot to mention when you are deciding where to inject test signals always best to try to get both intra-board molex connectors and the lead wires involved so in this case the very best place to inject test RIF signal is actually at TP-2 on the RF board. I inject -53dBm @ 8.830 mhz there and will get a nice loud tone out speaker and around S5 S-meter indication. This way you are getting the pin to pin pad solder connections at molex connector 5, the pin to pin mating interface surfaces at conn 5, the crimps on the lead wires at conn 5, the lead wires themselves to the IF board Conn 6 and the same set of places where you can have bad connections at Conn 6.

If weak then re-inject at Conn 6 on IF board. If no change, then you no the problem isnt in that interconnecting path where there are so many opportunities for bad high resistance connections. Then you proceed down the IF and Mixer trail. Only problem is KW didnt provide very many test points so have to carefully apply signals with sharp pins, SMT prods, micro grabbers etc.

Yup you are spot on Terry. I start to see a reduction in output when at -5.95vdc and at 5 watts output when I reach -6.89vdc. I think I will build a voltage divider so my min to max on the adjustment pot falls in that range. Makes it easier to tune my amp. Now I will see if I can make sense of adjustment step 31 for the ALC. Looks like I need an audio generator.

Thanks and Merry Christmas

OK I'm an old timer (licenced since 1956), but I get really bugged by stories like this.
It is becoming very clear that the old servicing industry is practically dead. Board exchanges
seem to be the best they can do.
The failure of the receiver makes me VERY concerned that they were not using a proper dummy load on the TX. That could certainly blow the front end FET's, and possibly other bits too.
Trying to keep a hybrid going must be a real nightmare for relative beginners and would probably be quite impossible without this groups good work.

It must be very hard to get into electronics these days as the technology has become so mature that "tinkering" has become next to impossible. For example my son (45) became, very wisely, a software engineer. Even though he was brought up around electronics all his life.
Happy new year to all.

50656. TS-830S Freq Shift in CW

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-24 22:50:55 UTC
From: kc5dfp@...
Topic: 50656 Message: 50656

Hello All.

I'm new to the group and this is my first past.

I just picked up a nice TS-830S, which I was tinkering around with due to distorted transmit audio. I slightly loosened and retightened all the screws in attempt to get better grounding, but then I noticed something strange.

I get about a 8KHz shift (increase in freq.) when I put the mode switch in the TUNE position (all other positions read the same freq.). Also when in either the CW wide or narrow modes, when I transmit I get the same shift. It's like working cw split, but I don't have an external VFO hooked up (I do have a vfo-240), nor is the RIT/XIT on. One more thing, the shift DOES NOT happen in USB/LSB at all.

Also, I did retune the oscillator trimmers on the PLL board; TC-3 USB and TC-2 LSB, as in another post it helped clear up the distorted transmit audio (which it didn't in my case). These appear to not effect the shift, so I think there is something else causing the strange frequency shift.

Any insight is greatly appreciated.

Thanks.

Joe

Joe,
Are you sure the frequency is shifting 8kHz, or is it shifting 800Hz?
If it is the latter (800Hz) that is NORMAL in "tune" and when set to CW-N or CW-W and transmitter is keyed.

May I suggest that you get a copy of the TS-830S Instruction Manual and become familiar with the controls and what is normal. You can find a good quality one at: n6wk "dot" com. Look under the Kenwood files. Look at Pg 10, #18 MODE SWITCH "tune."

Hi Robert,

Pops are not good news but can be better than some other things such as flames!

The first thing I would check is the supply voltages on the rectifier board. If the +14V went away it would kill the RX. Be careful because there are some very high voltages on that board that can kill. If you aren't comfortable making those measurements get some experienced help, maybe from a local ham club. It looks like you can also check pin 2 of the transverter socket for 14V (I'm looking at the TS-520 schematic but I don't imagine the 520S is different in this regard).

The first thing I usually check on any old piece of gear that I work on is the power supply.

73,

Bill, WA6NEQ

Date: Wednesday, December 24, 2014, 5:32 AM

From Bill, WA6NEQ
Sorry to hear about the loss of receive in your
rig. Have you verified that it still transmits after the pop
and with no receive? Or is this a case that while they were tweaking the
transmitter, they heard a pop, noticed that the receive was
gone, shut it down, and called you?

Bill, thanks for the response.
 It was pretty much the second scenario. I think they
chased a few things after that, but my impression it was
going to be a lot more $$, so they called me and shut down
trouble shooting. I hope to get more info when I pick up
the unit next week. Will post with more details.
From Jimmy WB2KNR
DO U HAVE A
CONTACT PHONE NUMBER YOU CAN BE REACHED AT?

Thanks for the offer. I haven’t
picked up the rig yet, but would truly appreciate the
assistance with troubleshooting. Will shoot you my number
off list.

From Wes, N9KDY
Appreciate the feedback. I have
been drinking from the knowledge firehose since getting my
general, spending just about every free moment tinkering
with antennas, doing research, etc. Challenge so far has
been finding good, hands-on electronics training locally and
haven’t been successful so far with the club (another
story). That being said, I am continuing on my education
however I can get it. I am working on an old shortwave
radio, attempting to bring it back to life (a low risk
tinkering project), and I built a DG-5 replacement from
plans/circuit board. For the rig, I will get a list of the
issues wrong with it and assess from there. In the
meantime, have printed a large format copy of the schematic
and some of the transmit and receive diagrams to familiarize
myself with the details. If you all have the patience for
my questions, I think I will give it a go.
Thanks all73,Robert/KD0YMC

Hey Joe.

Thanks for the reply. After looking at it again it's 800hz. I do have a original manual, and the section you mentioned doesn't indicate an 800hz shift. I'm still thinking something changed with the rig. Tuning in a CW signal on a frequency, and transmitting 800hz higher doesn't seem right. Using another receiver along with the TS-830S I can tune both receivers to the same pitch on a CW signal, but when I transmit on the Kenwood and listen on the other receiver the transmitted tone is higher, about 800hz.

Anyway, Anything further on this is greatly appreciated.

Best,

Joe

Joe,
As stated earlier, the 800Hz shift is normal. Here is what Pg 10 #18 of my TS-830S Instruction Manual says:
  TUNE.....This position provides reduced carrier and shorted key line for transceiver tuning.....
Frequency is shifted approximately +800Hz from the USB or CW receive frequency. This is the actual CW transmit offset. This feature allows you to Zero-Beat an incoming CW signal.
Also, you can refer to Pg 20, (5) CW Operation Fig 4-13.
Say you set your frequency to 14.175.00MHz. You turn the mode switch to "tune," the digital frequency readout will now show 14.175.80MHz. Turn it back to anything else, and the frequency will again show 14.175.00. If mode switch is turned to CW-W or CW-N, the frequency will still show 14.175.00 UNTIL you key the transmitter. The as long as the transmitter is keyed in CW, the frequency will show 14.1750.80. It will not shift up +800Hz in USB or LSB during transmission.
Again, this is normal

I thought you were using this to run QRP. Didnt know wanted to reduce power to drive Linear Amp.

I would opt for a simple 3db attenuator made from thick film resistors. Can be manually switched, relay switched or just left in the line at all times as will have minimal effect on receiver. Last couple pages of this article show manually switched pad. Using attenuator keeps jack freed up so can still use ALC from the amp to the exciter.

http://www.ad5x.com/images/Articles/HiPwrPad.pdf
http://www.ad5x.com/images/Articles/HiPwrPad.pdf

Yes a good stable and accurate Audio Generator is a must (accurate and stable level very important). DDS Function generators are not too expensive these days. Probably the best way to set the SSB frequency response (carrier oscillator set point) is to use Audio Gen/Wattmeter method.

Can be physical unit or might look into some of the software units. Go thru the service manual and note every step that uses audio generator and what level is required. Then look at specs of units you are considering to make sure it can operate at these levels. For years I had to use a frequency counter and a true RMS audio vtvm to confirm my old analog sine wave generator was putting out what its dial and step attenuator said and it never was accurate and would change up or down as i went up and down frequency. I finally got a decent arbitrary waveform generator and makes the job so much easier.

Joe/Tom,

Thank you for the replies; I appreciate them greatly.

I do have an original manual and it does not indicate the frequency shift, BUT I did download a copy from the net which sure does indicate the shift! I guess my radio is working just fine, and the manual I have is an early edition.

Seeing I've only had the radio for less than a week there's a getting familiar period, and I should spend more time with it, but so far I think it's great. I'm pretty impressed with it seeing it's old technology, and comparing to other radios I've had, it's measures up well.

Again, I appreciate both your responses and for helping me understand the radio a bit more.

Take care and 73s (and Happy Holidays!).

Joe,
You are welcome. One of the nice things about the 830S, is you can monitor your signal. I like to use headphones, and engage the "moni" button. You should be able to hear if there is any distortion as reported. There are many reasons this could happen...RF feedback, incorrectly wired mic, too high of mic gain.
Happy Holidays

Good suggestion on the attenuator, Terry. I built the AD5X unit and use it between my 820S/590S and my ALS-600 amp. Works very well and straightforward to build using his instructions and parts list. It stays in line and when the amp is not turned on, it is bypassed. I take the 12V to operate the relay from the ALS-600 12V outlet. As you say, no noticeable effect on receive on either rig when operating.
Merry Christmas to all!

Hey Joe.

Thanks. I've used headphones to monitor my audio and the only way to get rid of the distortion is to lower the MIC level, but then this hardly drives the radio and puts out barely 30 watts. I'm suing a MC-50 and a hand mic and both produce the same result. Resetting TC2 & TC3 (LSB/USB) on the PLL board cleaned up the audio a bit, but not completely/ I highly suspect it's RF interference as the audio is a bit warbley too. I'm going to check all the connections and grounding points, as well as doing some net searches, and go from there. Any insight is welcome.

Thanks Again.

I have noticed this as well in both my 530/830, that the mic gain increases the mic sensitivity and back ground noise starts to rise a lot? Back the gain down and the background is gone, but no power. I haven't noticed this in my other radios (Tempo 2020, Yaesu 901/902) as much. Could this be in the mic pre-amp circuit design?
Also, just holding/touching/bumping the MC-50, amplifies tremendously. At the last Kenwood net, Mark said he could hear the fan noise from my 530, but that was my shop heater across the room from the station. Testing my 830 last night demonstrated the same thing. Extremely high mic sensitivity.

Joe,
What you are most likely doing is over driving...and causing splatter around your center frequency.
If you are not using a "peak reading watt meter" you will not get a true reading of your RF output. If you have mic gain set correctly...ie...speaking about 1 to 2 inches or so from mic...in a normal tone/volume...the meter switch set to "ALC"...transmit and advance the "MIC" control just so the needle deflects up off the resting position on voice peaks. Seeing 30 watts or so when on SSB using an "averaging" type watt meter(most common) is fine. Overdrive, splatter...and other signal annoyances, are not good ham practices.

Well,, actually I need the mod for QRP (future use) and the amp. This is an old Heathkit SB230 solid state (8873) amp I resurrected from its dusty grave. It had a new transformer in it but was wired wrong. It had the receipt for the transformer stuck in it and was dated 1986. So I assume the amp has been idle since the new transformer was installed wrong and wouldn't work. The manual states to slowly increase exciter output power and tune the amp at 100ma IP intervals until 500ma is reached. About 5 steps in all. So I need to be able to vary output of the 830S as I bring the amp up to 500ma IP in steps. The 830S is outputting about 75Watts when the amp is at 500ma IP. Anything more is too much. I know I could do this with the carrier level in CW, but would not be any good when I switched to SSB, soooo the QRP mod was needed to slowly bring the amp IP to full output.. I have built a simple voltage divider with the adjustment in the -5.75vdc to -7.1vdc range. This gives me 0 - 100 watts on my 830S. Probably not the same for all units but works great for me. This is the first time I have messed with a linear amp so I am tuning it by the book.

I got a bit off the Kenwood subject here but I know it must be hard for the experts to answer questions when they don't have the rig in front of them. I take no offense to being told I am wrong and appreciate all the input. Terry gives long answers and I love to read all that extra stuff he adds. We are not in a repair world anymore, Everything is throw away and buy a new one. I don't know the future of this hobby but I don't think it's in computers. They will FAIL when you most need them.

MIC GAIN JUST DOES THAT, Increasing the gain of the mic amplifier and thus the level of whatever sound reaches the mic, weather it is your voice or room noise. I would get closer to the mic and close the door of the ham shack, or hang sound deadening cloth curtains on the walls. I NEVER have this problem since I only operate on CW !!!:D :D My radio is Ham Radio...CW is Real Radio

Subject: Re: [TS-520_820_530_830] TS-830S Freq Shift in CW

  I have noticed this as well in both my 530/830, that the mic gainincreases the mic sensitivity and back ground noise starts to rise alot? Back the gain down and the background is gone, but no power. Ihaven't noticed this in my other radios (Tempo 2020, Yaesu 901/902) asmuch. Could this be in the mic pre-amp circuit design?
Also, just holding/touching/bumping the MC-50, amplifies tremendously.At the last Kenwood net, Mark said he could hear the fan noise from my530, but that was my shop heater across the room from the station.Testing my 830 last night demonstrated the same thing. Extremelyhigh mic sensitivity.

Jan:

Where are you normally running the mic gain and experiencing this extreme high sensitivity with your TS830?

Also have you calibrated the ALC meter circuit Step 31 in the Service manual? You will need a calibrated Audio generator to inject the correct mv levels or a true rms AC voltmeter to confirm using correct levels.

Could have the ALC meter sensitivity set too low fooling you into thinking you have to increase mic gain to get active ALC meter indication.

The 830 is designed to be used with MC50 or MC60. About only mic I have found you have to be careful with is Shure 444D. I run both the KW mics and the Shure is lot hotter. With my voice I cant run mic gain above #4 position. Not very scientific but a MC-50/MC-60 open circuited will put out approx 15mv using "five-five-five" and not real close talking it. The Shure 444D using same method puts out 25mv to 30mv. The Shure is good mic for communication presence audio and chasing DX barefoot. With or without speech processor I find can break more pile ups using it. Just have to watch where you set the mic gain.

The current Issue of QST (January) has an excellent article on RF in the shack. The need for "bonding" beyond basic ac safety grounding is well written. We all have more devices in our shacks than was the case pre-computers.

Hey Joe.

Thanks. I've used headphones to monitor my audio and the only way to get rid of the distortion is to lower the MIC level, but then this hardly drives the radio and puts out barely 30 watts. I'm suing a MC-50 and a hand mic and both produce the same result. Resetting TC2 & TC3 (LSB/USB) on the PLL board cleaned up the audio a bit, but not completely/ I highly suspect it's RF interference as the audio is a bit warbley too. I'm going to check all the connections and grounding points, as well as doing some net searches, and go from there. Any insight is welcome.

Thanks Again.

Joe

Terry,
No, I haven't, so I'll try doing that calibration maybe tonight.
I still haven't found my low RX signal problem in the 830. I'm going to
just use the 830 as it is and again look for the problem in a month or two.
I did do a signal level traceability test, Terry....but not sure what to
think about it. Its not agreeing with the service manual's levels in the
front end.

Has anyone tried this for QRP? Will it work on the plain 520??

The TS-520S can be operated QRP down to a few milliwatts with simple modification. Apply negative voltage on the ALC pin of the ancillary socket.

Modification consists of a 220K Ohm pot and a 9V battery.
Positive terminal of battery to ground (Pin 4)
Negative terminal of battery in series with 220K pot to ALC pin on socket.(Pin 6)

Maximum of 34 microamps drawn so battery should last a long time.

Thanks again,
Chad

Jan:

Is this a TS830 that had burned up L41? If so I know we discussed how to bench test the rewound L41 before installing in the rig but not sure if we discussed testing the BCB filter?

I have found 3 or 4 bad L1 2.7uhy chokes after an inadvertent transmit event that takes out L41. Sometimes you can even see it as the green body of this shunt choke will have a darkened brown/black ring around it.

I always test the BCB by placing the band switch in 160 meters, Drive control at 1200, and inject low level 1.9mhz into SO-239 and then measure RF voltage at S1-2. If you inject -43dBm should be able to peak approx 11.0 mv at S1-2. Now start running the frequency down and observe the roll-off of the filter. Should start to see level falling immediately and see about 1/2 voltage (5mv to 6mv) at 1.7mhz.

The BCB is a high pass filter that is in the off air signal path to prevent front end blocking if you live in an urban area that has strong broadcast band stations.

IF L1 is bad it shunts RF signals to ground and greatly alters the freq response characteristics of the BCB filter. Doing the roll off test prevents having to pull the choke to measure it. If you have the board out can inject test RF into TP-1 and measure output at S1-2. I have never found any of the other LC components of the BCB hurt other than L1.

50680. TS-520 Repair Progress Report

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-27 13:54:53 UTC
From: roberteleazer@...
Topic: 50680 Message: 50680

Early this morning I finally applied power - as in full AC power - to the TS-520 I have been repairing. At first I got nothing - turns out the shorting plug had fallen part way out. This was a bit of a surprise since I have never had a TS-520 or TS-820 come with the shorting plug installed!

Once the plug was in I got lights and sound - and better yet, no smoke. The audio output from the speaker is not very loud but sounded Okay. My $1.50 Heathkit SG-6 signal generator chose this morning to quit (should have brought the much better $10 HP one over to the bench) but I was able to copy 40 Meter SSB, and WWV at 10 MHZ was right bang on, all received with nothing more than an alligator clipwire plugged into the antenna socket and inside a metal airplane hangar with the door closed.

80 Meters was very quiet, and the 25 KHZ calibrate signal was weak, but on 7 MHZ and 14 MHZ the calibration signal was quite loud, but less so on 15 and 10 meters.

The high voltages coming out of the transformer were a little low, for example, the 400VAC measured as 350VAC, but the output of the HV board to the power amp section was 944VDC, so I guess that is working OKay.

The front panel meter does not seem to be doing much of anything and actually went down a bit when tuning in the strong calibration signals.

So, while there is still a lot to do, the rig is coming along not too badly and may actually get back on the air one day.

Thanks for all y'all's help, and Happy New Year!

Terry,
Yes, this is the 830 that we discussed back in (?) January or so, about troubleshooting my 830 RX front end. And this effort lead to my discovery of re-winding and testing the L41. I did pull my L41 and it tested just fine and as well as Q1. But I did a signal level trace measurement from TP1 to Q1 and I wasn't getting as high a signal level at Q1, so it has to be a bad component somewhere in that chain. I suspected the BCB high pass filter, but I didn't see any discoloring on L1 or L2, so I thought I needed to come up with a proceedure to sweep the filter. So, I'll proceed with your technique today after the Hybrid Net today. I'm now pretty sure its L1 after reading your post.
By the way Terry, I did the sideband, ALC and compressor alignments last night and my mic audio is much better! I'll do the same to my 530 later on this weekend.
Thanks again Terry, I couldn't have learned, what I learned, without your help.

OK Jan I wasnt sure as I see and discuss so many Hybrids with so many people it all starts to blur together after awhile!

Look at my website under Pictures and you can see a Spectrum Analyzer sweep of the BCB filter, but as mentioned you can just use a straight RF sig gen and RF millivolt meter or O-scope and test your BCB pretty quickly.

Only other elements in the path are the 8.830 mhz wavetraps and never seen one of those hurt either.

D2 transmit protection diode is usually good or bad. Never seen a leaky one. It is there to protect Q1 from your own transmit RF and not for ESD protection as some believe. It gets biased on by the IR drop across resistor R35 in the Driver tube cathode circuit when the 12BY7A is biased on in Send.

Terry,

I took a few days off for Holiday and family. I hope you had a very Happy Holiday!

Okay, performed step 11. The trimmer did indeed vary the uV level on Q4, but the low point I got was about 13 uV while the service manual suggests a 5 uV null, (meter is a Boonton 92B). While I was there, I checked the DC voltages at Q4 – all were close to those posted on the schematic.

The S meter is a puzzle. It indeed will not zero unless I drop the 9 volt rail to about 8.2 vdc, lowest I can go is about S 5 at 9v, (I double checked the voltage with my trusty Simpson 260 to verify accuracy). It also will not indicate any signal strength at 9 vdc – flipping AGC to off also has no effect it just stays at S 5. Things seem to act more normal at 8.2 vdc. I dropped the rail to 8.2 vdc and performed steps 12 and 13. The IF strip and Ant – RF coil packs were all pretty close before and all were able to be peaked. When that was all said and done went back and performed step 17. The meter zeros – Vr1 all the way CCW to get there. At recommended SG levels S meter reads about S 4, Vr2 fully CW, (same as with the calibrator BTW).

RF Gain control continues to have no effect. Also varying the 3.2 volt level has no effect on operation.

Regards

Tom

Subject: RE: [TS-520_820_530_830] Re: TS-530SP RF Gain

Did we discuss checking the Product Detector carrier null?

If not perform Step 11 of Service Manual. If carrier (carrier insertion oscillator or BFO in old days) is not nulled it will leak back thru L10 and couple thru C31 to the AGC detector diodes just as a strong off air signal would and will cause the AGC amp to be turned on and pull down the AGC bus voltage and cause a standing S-meter indication. Do this alignment step first. I always clean the trimmer pots and caps first with Deoxit and blow out with canned air and run thru range a few times as they can be pretty noisy and touchy. If you dont have RF millivolt meter can use O-scope to adjust the null. Make sure you are adjusting on the Product Detector and not the Balanced Modulator.

Regards the S meter raising the 9vdc regulated supply to 9vdc level should not affect ability to zero the S-meter. Ordinarily you would align the IFT and do the Coil Pack alignment before calibrating the S-meter. You can skip these steps if confident rig was pretty well aligned at one time. Try perform Step 17 of the Service Manual to see if you

can get the S-meter aligned. Dont skip any part of these steps. (8dB = -105dBm and 40dB = -73dBm). If have trouble with Step 17 I would go ahead and do Steps 12 and 13 and then repeat Step 17.

Regarding AGC bus voltage I assume you read 2.1vdc on AGC bus with rig on dummy load, RF gain full CW, and I believe that you previously reported that RF-1 is set at 3.2vdc. That is pretty big drop in voltage for the Heath 11meg vtvm to cause. I would have expected around 2.6 vdc or so. That .5vdc lower control voltage on the Gate 2 of all the IF amps makes big difference in gain. We need to figure out why the AGC bus is at 2.1vdc and not 2.6vdc. Lets eliminate Product Dectector carrier null first.

Tom

Since radio has been in your possession did it work correctly and then develop this problem or has it always acted this way?

I think you mean 13mv and not 13uv. About best I have ever seen is 2mv. Must have the RF gain backed all the way down so you are shutting down Q4. Dont want any RIF involved. Now can measure the Product Detector Carrier level at Drain of Q4. Drain is top right lead. Should be able to adjust TC-2 trimmer to get carrier nulled to close to 2mv and certainly less than 5mv. When you turn RF gain put full CCW to perform this step does the S meter peg hard full scale? It should. If it does not you cannot do this step.

When you say RF gain doesnt do anything not sure what you mean by that? Do you mean it Does Not cause the S meter to move upscale from its standing S5 to full scale deflection with pot turned full CCW?

It is normal to have No S meter action with AGC in OFF. This is because AGC amp is back biased with -6vdc and detector diodes cant turn it on so it cannot pull down the AGC bus voltage and cause S meter to drive upscale.

Are you saying that the S meter sits at S4 or S5 and does not go up scale with any of the following:
1. Reduced RF gain pot with AGC on Slow or Fast or OFF positions
2. Turn on the Marker signal
3. Inject signal into SO-239 with RF sig gen

Does VR-2 S meter span adjust trimmer pot have any effect on reading?

I recall you measuring the RFG voltage at the IF board and able to vary voltage from 3.2vdc to approx 0.80vdc by reducing RF gain pot from full CW to full CCW position. If that is true RF gain pot is doing exactly what it is supposed to do.

I would set 9vdc rail back to 9vdc as it belongs. I am beginning to suspect something wrong with S meter FET Q7. I think I mentioned they normally are good or bad and dont get weak, but I wonder if someone has replaced the factory 2SK19GR with a sub. Cannot use just any old generic FET in this application. And have to be careful about lead transpositions with a sub. Sometimes on ebay can find NOS Toshiba original FETs. Other option is to buy a spare IF board and swap out.

Suggest you also measure the AGC bus resistance to chassis ground with rig downpowered. Should be approx 2.2 meg ohm.

I think we also applied 3vdc from batteries to power the AGC bus and I think you said the gain picked up as it should. You of course would have no AGC action and no S meter reading as batteries are low Z power source and the AGC amp cant pull them down. What this test proves is nothing wrong with any of the gain controlled mosfets.

Most common thing to pull down the AGC bus and cause a standing S-meter reading is a shorted Meter FET, but normally it pulls bus down very low and pegs the S meter. A standing S4 or S5 says there is a short but not a hard fault. Maybe a leaky AGC timing cap (3 on the IF board and 1 on the RF board) or leaky meter FET if there can be such a thing?

Sorry so disjointed but I am losing track of what we have done. Hard to troubleshoot this way.

Terry K9TW

I would have to look at the ALC circuit to see what resistance is causing the increased decay of the 9 volt battery.

The external circuit has a 200K pot in series with the battery. If you removed the connection from the pot's wiper to pin 6, the typical current load on the 9 volt battery would be approximately 45ua (9 / 200000 = .000045). That should last more than a month.

Hi Sid,

You have two very nice meters already. They will certainly do everything you could ever want on a radio work bench.

However, if you really need a DMM then why not look for one that might augment some of the functions you already have with your two analog meters. Some features that come to mind are;

Resistance checking is a whole lot easier with a DMM so that's a positive.
A continuity beeper is also good. Check the max resistance before the beeper quits working.
A diode check function is a neat thing to have but of course you can already do that with your meters.
Look for some kind of frequency measuring capability - audio frequencies for a start. I've seen some meters that go to 2MHz.
How about inductance and capacitance measurements? Check the minimum range on each and check the test frequency the meter uses. There's not much use have a LC meter that won't read below 2 Farads or 2 Henries.
3 1/2 digit display is pretty normal but 4 1/2 digits is great for measuring small voltages.
Another cool thing to look for is a relative mode. This means you can measure a voltage, hit the zero button and make your adjustment and see how the value changes relative the initial value.
Look for an integrated bar graph in the display. Looking at a bunch of number dance on the screen while you adjust something is the pits. With the bar graph you can see if you're adjusting in the right direction.

Plenty of DMM's have some or all of these features and you can get them for around $50 to $100 or more depending on your budget. Here in Australia you get a lot of meter for $100 to $150.

I think of more importance it to make sure it comes with a good manual (in proper english), with a detailed list of specifications and check the build quality including the probe sockets and the leads. How easy is it to change the battery or the fuse(s). Are the fuses easy to get if you need more? Some of those bigger DMM fuses are outrageously expensive. These points will usually give you a pretty good indication of the quality of the meter. Also ask if you can get service and support from your seller if you need it.

Regards

Lou

At one point on Ebay you could find the fluke 27 US Army DMM for very cheap. They were surplused in great quantities and most had recent calibrations.

You can also keep an eye out for some of the old 8205 meters. I have also ran into a few deals on the 77. I paid dearly for mine, there are deals out there if you look for them.

There are a number of Fluke 27's being sold on eBay, both new and used, some working and some NOT working. There's one seller that has one for sale in working condition, with probes, for $49.99 plus shipping (see ebay seller ad #281523448954 for further details).

When purchasing use DMMs, pay close attention to the seller's description. Quite often buyer miss important comments about the item being sold by not reading the description. If the item says something to the affect of "the meter does not power up...", that could mean the fuse is blown or it could mean the meter is damaged beyond repair and could cost a lot of money to get fixed.

If the meter being sold on eBay is working but doesn't have the Banana tip probes, you can buy new Banana tip probes on eBay. Just pay attention to the probe specifications, not all probes have an AC/DC voltage rating of 1KV.

The Fluke 27 service manual can be downloaded from my website:

www.w5rkl.com

Click on the Manuals, Docs, and Mods link at the top of the page then scroll down to the Fluke manuals list and click on Fluke 27 link.

Sid:

This summer I bought a Fluke 175 True RMS Digital Multimeter that more than meets my needs for $250. This replaced a Heath DVM that I built over 35 years ago. Have kept it since it is still in calibration, although it is clunkier to use. hi hi

I also bought a nice set of silicone test leads (spring hooks, aligator clips and probes) from franky@... for about $20 that came via China Post. I use these instead of the vinyl leads (-- how cheap of Fluke!) that came with the meter.

There are used industrial grade Fluke FT87 series DVMs on eBay but I decided not to take a chance. And besides, the 175 comes with a limited lifetime factory warranty.

FOR SALE: 2 year old Kenwood TS-520S with matching 520 external VFO w/cable and matching TS520 Speaker. Internal PS, runs off of 125vac.

Equipment was purchased in 1977 and put in the closet when owner went SK in 1979. Equipment had plastic dust covers on all, all this time. Almost perfect.

Does have 2 years' worth of use, plus a little plastic rubbing. Leather stitched handle looks brand new. Operates great on all bands, 100 watts output. Does not have WARC bands.

Original Owner's manual, Original Sales receipts from Nov 1977. Original Log book 1977-1979.

Absolutely gorgeous! Should not go to a new ham as "first radio". Would like to sell complete for $450. Shipping extra.

OR trade for a later model Kenwood or ICOM; 440SAT, 450SAT, 735. Equipment is to support a public Middle School HAM Club.

Photos available. In Aiken SC area

50699. Kenwood Hybrid Net Update (December 28, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-28 19:18:44 UTC
From: Mark Gilger
Topic: 50699 Message: 50699

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 27 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
3 running TS-530(x)
7 running TS-820(x)
6 running TS-830S
0 running TS-511
0 running TS-511
0 running 599 twins

I was running my TS-830s & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
18 stations checking in under fair band
conditions. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, and Jimmy, WB2KNR . I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88

December 2014, Saturday☐s net total 92, Sunday☐s total = 86 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

50700. TS-520 Filament Question

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-12-29 19:29:36 UTC
From: roberteleazer@...
Topic: 50700 Message: 50700

I have discovered that there is almost no power going to the power amp tube filaments on the TS-520 I am working on.

I measure 60 ohms across the heater power switch, which might explain at least part of the problem.

But does anyone know where the filament for the 12BY7A is depicted on the TS-520 schematic? The schematics I have only show the 6146 filaments.

Thanks,

Robert
WB5WSV

Robert,

All you have to do is follow the driver and both final unit filament wiring back through the 12 pin power plug to the power transformer. The internal 12 pin power plug wiring is shown with all the jumpers on the TS-520 and TS-520S schematics.

Depending which TS-520/520S/520SE you have, the 12VAC secondary terminals will be labeled either 12.4 or 12.6 on the power transformer's secondary schematic.

The TS-520 and TS-520SE schematics show the power transformer's 12VAC secondary filament and dial AC voltage terminal as 12.6 while the TS-520S shows the same power transforemr's 12VAC secondary filament and dial AC voltage terminal as 12.4.

The 12.4 or 12.6 winding terminal connects to pin 10 in the 12 pin power plug. The power plug Pin 10 has a jumper to pin 7 which, when plugged into the rear 12 pin connector, connects directly to the dial lamps and the Heater switch in the TS-520 and TS-520S.

There is no Heater switch nor a 12 pin power plug/connector on the TS-520SE so pin 7 connects directly to the dial lamps and the driver and both final tube filaments.

Robert,

I don't know how you missed the 12BY7 filament on the RF Unit so I cut and pasted the RF Unit that clearly shows the 12BY7 filament at the RF Unit's "H" terminal. The below RF Unit schematic is the same on all 3 TS-520s.

You simply follow the "H" wiring back to the 12VAC filament and dial lamp secondary. If you 520 has the 12 pin power plug/connector, the filament and dial lamp AC voltage is routed through pin 7 to pin 10 and terminating at the 12.6 or 12.4, depending on which 520 you have, secondary winding terminal.

Robert,

Just in case you can't find the 12VAC filament and dial lamp secondary winding, I've cut and pasted the secondary along with the 12 pin power plug and plug wiring.

Note how the 12.4 terminal connects directly to pin 10 on the power plug. Looking at the internal wiring of the power plug you will see that pin 10 connects to pin 7. Looking at pin 7 you see that pin 7 connect to the 4 dial and meter lamps and the Heater switch as well as to pin 4 on the remote VFO socket. Pin 4 on the remote VFO socket provides dial lamp and relay voltage to the remote VFO.

I have a high resolution schematic that contains receive and transmit voltages that you should have. You can download that high resolution schematic from my website's Manuals, Docs, and Mods page. Simple scroll down to the TS-520S listing and click on the high res schematic link and download it to your computer, it's in pdf format.

Topic: 50689 Message: 50704

Timely info, I am looking for a decent multimeter for the bench.

What other equipment would be a necessity for basic repairs for a Kenwood Hybrid? I have a decent soldering iron set up, a basic DVM, and a dummy load. I have seen references to VTVM, RF Voltmeter/probe, signal generator. I have seen reasonably priced Heathkit VTVMs and signal generators on Ebay, but wonder about folks opinion on those. I know there are lots of variables in that ask.

I am still waiting on picking up my 520s from the shop. Weather on the front range in Colorado is rough this week. You will recall that I was talking about selling or salvaging. I am going to give it a try on the troubleshooting/repair.

One of the early projects will likely be a re-cap. I don't think it had been done yet. I will get back to the list on the list of issues after I pick it up from the shop.

Regards,
Robert/KD0YMC

50705. Re: [TS-520_820_530_830] TS-520 Filament Question

Mike:

I was able to find the 12BY7A filament in the TS-520S schematic very easily but since I am working on a TS-520 I wanted to use the data for that rig. If you say the two RF boards are the same, that's good enough for me. But I never have been able to find the filament on the TS-520 schematic, either the main drawing or the one for the RF board.

I already did some tracing of the schematic and set wiring, and tomorrow I guess I will take the front panel off so I can access the heater power switch. Perhaps then I can confirm that the switch has failed. What does not make sense so far is that the 60 ohms of resistance I measure in the switch should not affect the reading at the 6146 sockets given that none of the tubes are installed at present and thus current flow should be almost nonexistent.

If the Heater Power really did fail I am considering installing a regular DPDT toggle switch on the back of the set. I might then wire in a Heater Power" light on the front; I think that would be better anyway. I wish we had an "SG Switch On" light on the front panel, too.

Another possible option would be to turn the switch upside down and rewire it using the two currently unused contacts, depending if the failure mode allows that.

One confusing measurement result is that I have 19VDC on one side of the Heater Power switch. I don't know where that comes from at this point. The regular 14V DC supply is running at 13.5VDC and I adjusted the 9VDC supply from the 8.4VDC it was to 9.1VDC.

Do you know why a DPDT switch was used for the Heater Power Switch? Of course, it is wired as DPST switch, but what do those other two contacts do? Is it associated with the switch between DC and AC power?

I have a high res TS-520S schematic but have been unwilling to trust it for troubleshooting and repairing a TS-520. It certainly is much clearer and has those voltage measurements as well. I have been copying segments of the TS-520 main schematic, pasting them into MS Picture IT, enlarging them and printing them out. The TS-520S schematic would be much better for that purpose if it was indeed usable.

Thanks very much!

Robert

Robert:

I just wrote a fairly detailed set of comments on type of test equipment needed and recommendations based on my experiences with extensive repairs to a TS-820S, as well as fixing one TS-520 and another TS-520 I am in the process of rebuilsing.

But Mozilla Firefox locked up and ate it all. And I lack the time and inclination to recreate it.

So good luck.

Robert

Hello all, I hope you all had a merry Christmas and to come a happy new year.Our radio club, (NOARS) And the Lorain County Wireless Operators, here in Ohio are looking for donations of 1950's radio equipment to set up a station in the old Lorain Harbor Lighthouse. Any donations will gladly be accepted.During the month of August 2015 we will be working stations from the lighthouse.

Message from Lorain County Wireless :
The Lorain County Wireless Operators are happy to announce the fourth straight year of operating from the Lorain Harbor Light August 14, 15 & 16 2015 in support of the International Lighthouse Lightship Weekend. This has become one of the waterfront's feature events drawing attention to the lighthouse. Each year the LCWO has provided either labor, supplies or advertising to support the Lighthouse Foundation's continued efforts to return the light to its status as "Jewel of the Port". This year will be no different. The foundation is returning the structure and contents to a 1950's look and feel. In doing so they have agreed to feature an operational or static display, to be on permanent loan, of a period amateur radio station. The goal is a operational station as other events will be structured around it much like the USS Cod or the Zoo's Rainforest. This will also expose the public tours and private events that take place in the lighthouse to amateur radio. So how can you help? We are looking for 1950's era equipment to build a station. We are also in search of a few hams that are proficient in the operation and maintenance of the equipment. We would like it to be fully operational or in a state that can be returned to operation. If you would like to help or have an equipment donation please contact Jeff Evans, KB8ZUN, at either kb8zun@gmail.com or 440-228-6081. This is a great opportunity to insure amateur radio continues to thrive and is in the public eye while paying back in honoring all the Elmers who helped us all in our continued growth in the hobby. You will also insure your callsign's lega-cy as a contributing force in the restoration of a National Landmark. 73, Jeff Evans KB8ZUN

Robert,

Do I know why they used a DPDT heater switch? Yes and you can easily see why by studying the TS-520 main schematic AND the DC to DC converter schematic!!

I recommend you do the following:

1. Go to my website and click on the Manuals, Docs, and Mods link at the top of the page
2. When the Manuals, Docs, and Mods page comes up, scroll down to the TS-520 listing and click on listing #1
3. When the page downloads (pdf format), go do page 50 and notice the "HEATER SWITCH" that connects the TS-520 power transformer's CT to B1 and B2 secondary winding.
4. Go to page 51 (main schematic) and look at the bottom right corner section of the main schematic and you will see a DPDT "HEATER SWITCH" labeled "S10". One half of the HEATER SWITCH S10 controls the application of the driver and both final tube filament voltage from the power transformer's 12.6. You have to trace the wiring from the center terminal of the HEATER switch through the power plug/connector pin 10 to pin 7 and from pin 7 down to the 12.6 terminal on the power transformer. The 12.6 terminal voltage is "AC" NOT "DC" so you have to set your volt meter to measure AC voltage.

I can't comment on why you see 60 ohms since I do not have a

The other half of the HEATER switch is used to connect the TS-520 power transformer "CT" terminal in the B1 and B2 windings to R1 on the DC to DC converter.

Now, click the pdf reader's page advance arrow twice (down arrow) and that will bring up the RF Unit schematic. You then click the pdf reader's "Rotate" icon so the schematic rotates "CW" ONLY ONCE! Now look along the right edge of the RF Unit schematic about a 1/3 to 1/2 way down and you will see a terminal labeled "H". To the "left" of the "H" terminal you will see "L7", C35, and a circle with 2 terminals labeled "4" and "5". L7 and C35 connect to terminal "5". Notice the sideways "V" inside the circle, that is the 12BY7 driver tube's filament schematic symbol!!!

Mike:
'

Yes, I did all of that circuit tracing - great minds think alike. And I guess that the answer is that they use direct DC power for the filaments when the set is running on DC and they run it off of the transformer when it is running on AC - rather than running it off the LV DC power all the time.

This morning I got the Heater Switch out of the front panel a ways and finally was able to measure across it. And it tests fine. I'll have to do some more tracing and testing to figure out why the filament power is not getting to the tubes.

Thanks, and Happy New Year!

Robert

Great news, my $50 TS820 is up and running. If the bloke I got it of new that the problem was that the shorting plug wasn't making contact he would be upset but my gain.
It does have a problem. On the lower bands it tunes up fine(125w CW) but try doing a tune up on 15 and 10mtr bands and it blows the power fuse. So any advise welcome

I just purchased a ts830s. Can anyone please confirm the wiring of the 12 way power block on the mains lead, please note this is for 240v. Its currently damaged but its looks like its was wired on pins 1,3,6. with
pin 1 to earthpin 3 neutralpin 6 live
I'm confused about if it matters about live and neutral positions. Its not clear in the manual about which wire is live and if it matters about them being reversed.

Attachments: 3 described; binary payloads are missing from this source WARC

Primary power, whether it's 120VAC or 240VAC, is connected to pins 3 and 6 and the 120/240 primary power switch is set to 240 for your AC primary voltage level.

The main power AC Mains plug wiring is shown below. Note the dotted line to pin 1. Pin 1, as seen in the main schematic AC wiring, is ground. Therefore, for 220VAC, the mains ground is connected to pin 1 and the other two 220VAC wires are connected to pins 3 and 6.

Below is the main schematic primary AC mains wiring diagram I cut and pasted from the TS-820 main schematic. As you can see pin 1 is connected to ground (chassis). The S21 AC select switch wiring is also shown. You can trace the wiring from pins 1, 3, and 6 with S21 set to 220, to see how the AC mains wiring connects to the power transformer.

The "AC SELECT" switch is set to the "220" position for your (UK) AC primary voltage and the ground for your 220 AC wiring is connected to pins 1, and the 220 hot wires are connected to pins 3 and 6. The fuse is changed to 4A for 220VAC instead of 6A for 120VAC as stated on page 14 (see below the fuse rating segment I cut and pasted from 820 operator's manual):

If the AC main wiring is correct to pin 1 (ground) and pins 3 and 6 (AC mains) then that's correct!! The damage could have been the result of not switching the AC select to 220 and using the wrong fuse. I recently purchased a Drake R4A receiver that a previous owner put a "20 amp" fuse in the fuse holder where a 3/4 amp fuse should have been!!! I recent purchased a Heathkit IM-5225 FET volt/ohm/ma meter and the fuse holder contained a blown fuse with "foil" wrapped around it so the meter worked. Thank goodness nothing failed in the meter that could have required the fuse to blow!!!

If you are getting 125 watts out into dummy load then you are not limiting the plate current to 200ma. The DC input power on this radio is 160 watts so max plate current should be close to 200ma.

Where and when in the loading procedure does it blow the fuse on 15 and 10 meters? Can you get the initial plate current dip in Tune Mode? Do you begin loading with the Plate Load capacitor plates fully meshed (full CCW position)?

From: Thomas Gugler
Topic: 50591 Message: 50715

Terry,

Okay, I'll try and keep this short and coherent.

I picked this radio up about a month ago from a local Club. It has had this issue since I got it. You are of course correct, I measured mv and not uf. Checked it again and the lowest I can null to is 13 mv. RF gain control has no effect on null reading. For that matter, what I mean about the RF Gain control having no effect is that it does not affect the S meter or receive sensitivity in any way – it does nothing. I did again verify it does vary the RFG from approx. 0.75 volts fully CCW to 3.2 volts fully CW.

I put the rail back to 9 VDC. S meter sits at S 5, never moves regardless of incoming signal strength, moving RF Gain, or turning off AGC. VR1 and VR2 are fully CCW in this state, advancing either one will allow the meter to peg to the right.

I checked Q7 and it appears okay, DC voltages were close to schematic specs. It looks original to me – marking is K192AGR.

AGC buss is indeed 2.1 VDC, and this is I believe the culprit. I measured the AGC buss resistance to ground – 500 ohms! I triple checked this measurement since nowhere near 2.2 meg. My VTVM probably isn't pulling down the AGC at all. I pulled the connector at the IF board that has the AGC line – infinity at the plug – the 500 ohm reading is on the IF board.

So, any common failure points other than Q7 I should check on. You mentioned 3 caps, so that will be the first place I go next.

Regards

Tom

Subject: RE: [TS-520_820_530_830] Re: TS-530SP RF Gain

Tom

Since radio has been in your possession did it work correctly and then develop this problem or has it always acted this way?

I think you mean 13mv and not 13uv. About best I have ever seen is 2mv. Must have the RF gain backed all the way down so you are shutting down Q4. Dont want any RIF involved. Now can measure the Product Detector Carrier level at Drain of Q4. Drain is top right lead. Should be able to adjust TC-2 trimmer to get carrier nulled to close to 2mv and certainly less than 5mv. When you turn RF gain put full CCW to perform this step does the S meter peg

hard full scale? It should. If it does not you cannot do this step.

When you say RF gain doesnt do anything not sure what you mean by that? Do you mean it Does Not cause the S meter to move upscale from its standing S5 to full scale deflection with pot turned full CCW?

It is normal to have No S meter action with AGC in OFF. This is because AGC amp is back biased with -6vdc and detector diodes cant turn it on so it cannot pull down the AGC bus voltage and cause S meter to drive upscale.

Are you saying that the S meter sits at S4 or S5 and does not go up scale with any of the following:

1. Reduced RF gain pot with AGC on Slow or Fast or OFF positions

2. Turn on the Marker signal

3. Inject signal into SO-239 with RF sig gen

Does VR-2 S meter span adjust trimmer pot have any effect on reading?

I recall you measuring the RFG voltage at the IF board and able to vary voltage from 3.2vdc to approx 0.80vdc by reducing RF gain pot from full CW to full CCW position. If that is true RF gain pot is doing exactly what it is supposed to do.

I would set 9vdc rail back to 9vdc as it belongs. I am beginning to suspect something wrong with S meter FET Q7. I think I mentioned they normally are good or bad and dont get weak, but I wonder if someone has replaced the factory 2SK19GR with a sub. Cannot use just any old generic FET in this application. And have to be careful about lead transpositions with a sub. Sometimes on ebay can find NOS Toshiba original FETs. Other option is to buy a spare IF board and swap out.

Suggest you also measure the AGC bus resistance to chassis ground with rig downpowered. Should be approx 2.2 meg ohm.

I think we also applied 3vdc from batteries to power the AGC bus and I think you said the gain picked up as it should. You of course would have no AGC action and no S meter reading as batteries are low Z power source and the AGC amp cant pull them down. What this test proves is nothing wrong with any of the gain controlled mosfets.

Most common thing to pull down the AGC bus and cause a standing S-meter reading is a shorted Meter FET, but normally it pulls bus down very low and pegs the S meter. A standing S4 or S5 says there is a short but not a hard fault. Maybe a leaky AGC timing cap (3 on the IF board and 1 on the RF board) or leaky meter FET if there can be such a thing?

Sorry so disjointed but I am losing track of what we have done. Hard to troubleshoot this way.

Terry K9TW

Bob….

Sure tell you are not an expert in making makeshift fuses! J

I used to work at a radio station here in Reno (Then it was KGLR FM) that was put on the air using high quality (sic) Sparta Equipment. We announcers would routinely over drive the off-air monitor speakers, blowing the slo-blo's. After a while, the supply of slo-blos ran out and had not been replaced, so we did the next best thing, we took out the blown fuses and wrapped them in the metal foil paper from around our cigarette packs. Worked like a champ but drove the chief engineer nuts! We had enough problems as it was, due to the Sparta equipment. (Did I say high quality {sic]) He was worried that would lt all the smoke out of the transmitter…where the speaker monitor circuit was! LOL.

Copper pipe indeed. (Oh wait, no one smokes anymore, so I guess the copper pipe *is* the next best thing…sorry…wasn't thinking!)

In 1960 I worked for a company that grew silicon crystals. We had an oven that used 3 phase 220 at 600 amps per phase. It started blowing the main breakers. To save the crystal the Chief Engineer put a piece of 2X4 in the breaker panel and locked the door.

It worked and the crystal was finished. It was for the nose of an IR guided missile.

The following day when the electricians replaced the breaker there was a lot of swearing!

I learned the 1/4" copper tubing trick when a production supervisor put one in an ultrasonic cleaner that was blowing fuses. It caught fire!

Yes certainly should not have standing 500 ohms on the AGC bus.

Very unusual for one of the IF amp dual gate mosfets to go bad.

Besides the meter FET and the gain controlled devices you also have the AGC amp transistor Q6 hanging off the bus at all times. I am inclined to believe it is the culprit and not one of the AGC timing caps. Either it is bad or is biased on all the time. Take a look at Q6. Also make sure you have good -6vdc to it and not just at the Molex Conn 12.

I agree with you Joe. Copper pipe, PLEEASSSE.
I want to fix the old girl NOT DESTROY it Fuses are there for a reason and I wont even use a slow blow fuse as the manual doesn't recommend it. 73

Thanks for reply. The info is really helpful. Can I just clarify whether or not it matters if live and neutral (hot wires) going to pin 3 and 6 are swapped around? The diagram isn't clear which way live and neutral are supposed to be wired and mine is currently wired with the fuse in the neutral line and the live going to main switch - which seems a bit odd to me! Many thanks and 73 Ian Macfarlane M6TSO

No it doesn't matter.

Having said that, it's best to have AC Hot connected to pin 3 and in series with the fuse. If a problem occurs that results in the fuse blowing, with AC Hot on pin 3, the fuse will keep AC off the power transformer primary windings..

If you reverse the connections, neutral on pin 3 and AC hot on pin 6, if the fuse blows for what ever reason, AC will still be present on the power transformer primary winding up to the fuse but no farther.

Bill,
Thanks for getting back to me.
It started out with low output. I resoldered the final board output base connections as well as the entire board.
Went through all the ground connections on the final, IF and RF boards as well as all the plug connections. Cleaned the carrier control and
checked all the transistors. I get good signal right up to the drivers.
With the mode in CW, Carrier up full, on 80M I get full output, 100W. On 40M, I get only 45W, and on 20M I only get 10W.
If I hold the send in transmit for 20 seconds, on 20M the output goes up to 95W from the initial 10. Same with 40M.
It’s like something is folding back the power initially, then after 20 sec it lets it go.
ALC voltage is OK at 2.3V. I do get an ALC reading on the meter
when in transmit.
Any ideas?

Walt, w3fnz

Hello All,
I need help with a 430s. Is
there anyone in the group familiar with this rig?
I couldn’t find a specific 430 yahoo group.

Thanks,
Walt, w3fnz

Walt,

Send me your email address, so we can take off forum. Is this a new thing that happened? When you say you soldered the final board, did you use wire for the through hole connections? Have you removed all the solder from the RF transistors and reflowed with new solder? Good tell tale sign is the solder around the rivets usually cracks and needs to be removed and resoldered with new. Also a common issue is the relays build up corrosion on the contacts which needs to be removed. There is a good youtube video of major faults and how to fix, basically show and tell.

Terry,

Saga continues. Looked at Q6, voltage on the base was off quite a bit from schematic spec. I did have -5.8 VDC bias to it. Pulled out Q6. Still measure 500 ohms on AGC rail. Did the old fashioned ohm meter check of Q6 and that test shows it's good – not definitive though so there may be an additional problem in that circuit. Since it's out I'll go ahead and replace it. I will need to source a suitable replacement since I don't have any 2SC1815's in the junk box.

So starting at the AGC connector I started lifting individual components from the buss line to find which circuit is dragging down the buss, (thank goodness for the Hakio 808). Everything good until Q2. When I lifted Q2, standing resistance went up from 500 ohms to about 200k ohms. So am assuming Q2 is bad. Will need to source a replacement for 3SK73 as well.

Since 200k is still too low, I guess I'll need to start the lifting process again to find what else is causing low standing resistance.

Regards

Tom

Yes certainly should not have standing 500 ohms on the AGC bus.

Very unusual for one of the IF amp dual gate mosfets to go bad.

Besides the meter FET and the gain controlled devices you also have the AGC amp transistor Q6 hanging off the bus at all times. I am inclined to believe it is the culprit and not one of the AGC timing caps. Either it is bad or is biased on all the time. Take a look at Q6. Also make sure you have good -6vdc to it and not just at the Molex Conn 12.
